Departmental
Findings of Fact and Order
New Source Review
NSR #25

FINDINGS OF FACT

After review of the air emission license application, staff investigation reports, and other documents in the applicant's file in the Bureau of Air Quality, pursuant to 38 Maine Revised Statutes (M.R.S.) § 344 and § 590, the Maine Department of Environmental Protection (the Department) finds the following facts:

I. REGISTRATION

A. Introduction

FACILITY	Verso Androscoggin LLC
LICENSE TYPE	06-096 C.M.R. ch. 115, Minor Modification
NAICS CODES	322121
NATURE OF BUSINESS	Pulp and Paper Mill
FACILITY LOCATION	Jay, Maine

B. NSR License Description

Verso Androscoggin LLC (Verso, The Mill) has requested a New Source Review (NSR) license to modify the No. 5 Paper Machine (PM5) and stock preparation system to optimize the productivity of specialty paper grades. The proposed project also includes changes to pulp mill production to support PM5 fiber needs.

C. Emission Equipment

The following equipment is addressed in this NSR license:

Modified Equipment

Equipment	Unit Type	Stack #
No. 5 Paper Machine (PM5)	Process Equipment	Multiple vents

Affected Equipment

Equipment	Max. Capacity	Fuel Type, % sulfur	Year of Install	Stack #
Recovery Boiler #1 (RB1)	2.50 MMlb BLS/day	Black liquor, #6 oil, distillate fuel, used oil, natural gas	1965	Combined Recovery Boiler Stack (CRB)
	315 MMBtu/hr			
Recovery Boiler #2 (RB2)	3.44 MMlb BLS/day	Black liquor, #6 oil, distillate fuel, used oil, natural gas	1975-1976	Combined Recovery Boiler Stack (CRB)
	405 MMBtu/hr			
No. 1 Smelt Dissolving Tank (SDT1)	2.5 MMlb BLS/day	N.A.	1965	SDT1
No. 2 Smelt Dissolving Tank (SDT2)	3.44 MMlb BLS/day	N.A.	1975-1976	SDT2
Lime Kiln A	80 MMBtu/hr (fuel firing)	Fuel oil (including #6 fuel oil, distillate fuel, specification used oil and off-specification used oil), propane pilot gas, and natural gas	1965	LKA
	248 tons/day calcium oxide (CaO)			
Lime Kiln B	80 MMBtu/hr (fuel firing)		1975	LKB
	248 tons/day calcium oxide (CaO)			
A Slaker and Causticizing Sources	248 tons/day CaO	N.A.	1965	Both vent inside a building; fugitive emissions
B Slaker and Causticizing sources	248 tons/day CaO		1975	
A Bleach Plant	1819 ADT/day	N.A.	1965	Bleach Plant Scrubber Stack
B Bleach Plant	909 ADT/day	N.A.	1975	
Regenerative Thermal Oxidizer (RTO)	8.0 MMBtu/hr	Propane, negl.	1995	RTO
		Distillate Fuel, 0.0015%		
		Natural Gas, negl.		
Wastewater Treatment Plant (WWTP)	N.A.		1964	Fugitive
B Diffusion Washer	N.A.		1975	Fugitive and washer system vents

Equipment	Max. Capacity	Fuel Type, % sulfur	Year of Install	Stack #
HVLC Source Group	Consists of emissions from multiple process units, collected and incinerated in the RTO			
LVHC Source Group	Consists of emissions from multiple process units, collected and incinerated in the Lime Kilns			

D. Application Classification

All rules, regulations, or statutes referenced in this air emission license refer to the amended version in effect as of the issued date of this license.

The application for the modification of PM5 does not violate any applicable federal or state requirements and does not reduce monitoring, reporting, testing, or recordkeeping requirements.

The modification of a major source is considered a major or minor modification based on whether or not expected emissions increases exceed the "Significant Emission Increase" levels as given in *Definitions Regulation*, 06-096 Code of Maine Rules (C.M.R.) ch. 100.

The emission increases are determined by subtracting the baseline actual emissions preceding the modification from the projected actual emissions. Baseline actual emissions are equal to the average annual emissions from any consecutive 24-month period within the ten years prior to the submittal of a complete license application. The selected 24-month baseline period can differ on a pollutant-by-pollutant basis. Verso has proposed the following 24-month baseline periods from which to determine baseline actual emissions from the emission units modified or affected as part of this project:

Pollutant	24-Month Baseline Period
PM	January 2009 – December 2010
PM_{10} and $PM_{2.5}$	June 2009 – May 2011
SO_2 and H_2SO_4	January 2010 – December 2011
NO_x and VOC	June 2013 – May 2015
CO	July 2012 – June 2014
Pb	April 2008 – March 2010
TRS and H_2S	April 2011 – March 2013
CO_2e	June 2009 – May 2011

The results of this baseline analysis are presented in Tables 1 and 2.

Projected actual emissions are the maximum actual annual emissions anticipated to occur in the ten-year period following completion of the proposed project. The production rates for all of the modified and affected units were calculated based on the targeted pulp production rate and known numerical relationships between pulp production and other materials at The Mill (such as black liquor solids, calcium oxide, etc.). These production rates and emission factors for each emission unit were used to determine projected actual emissions, as summarized in Tables 3 and 4.

Total Projected Actual Emissions	**158,774**	**160,522**

An applicability determination was made based on the total project-related emissions increases from PM5 and the affected emissions units. The total project-related emissions increases were calculated by subtracting the baseline actual emissions from the projected actual emissions for PM5 and affected units. Because the future projections of pulp production at the mill were already accounted for in Air Emission License A-203-77-22-A (issued May 15, 2018), emission increases from affected units addressed in that license were also subtracted to prevent double counting of affected liquor cycle source emissions. This analysis is presented in Tables 5 and 6.

The projected modification to PM5 is determined to be a minor modification under *Minor and Major Source Air Emission License Regulations,* 06-096 C.M.R. ch. 115 since the changes being made are not addressed or prohibited in the Part 70 air emission license. An application to incorporate the requirements of this NSR license into the Part 70 air emission license shall be submitted no later than 12 months from commencement of the requested operation.

II. BEST PRACTICAL TREATMENT (BPT)

A. Introduction

In order to receive a license, the applicant must control emissions from each unit to a level considered by the Department to represent Best Practical Treatment (BPT), as defined in *Definitions Regulation*, 06-096 C.M.R. ch. 100. Separate control requirement categories exist for new and existing equipment as well as for those sources located in designated non-attainment areas.

BPT for new sources and modifications requires a demonstration that emissions are receiving Best Available Control Technology (BACT), as defined in 06-096 C.M.R. ch. 100. BACT is a top-down approach to selecting air emission controls considering economic, environmental and energy impacts.

B. No. 5 Paper Machine

Verso plans to grow its specialty products business, including bleached and unbleached grades of specialty papers. To this end, Verso has proposed various mechanical, piping, electrical, and control system modifications to the stock preparation system and PM5 to address current bottlenecks for the grades of paper being produced. This will allow for increased production of specialty grades.

BACT Findings

For modified emission units, BACT shall be applied to the regulated pollutants that will be emitted in greater amounts as a result of the modification [06-096 C.M.R. Ch. 115]. Therefore, the BACT analysis for the PM5 project addresses PM, PM_{10}, $PM_{2.5}$, and VOC emissions.

1. Particulate Matter (PM, PM_{10}, and $PM_{2.5}$)

The paper making process requires large amounts of air for removing moisture and particulate released during the process. The air utilized is primarily discharged from three locations on the paper machine: the former/wet end, the drying process, and the dry end. The generation of particulate matter is inversely proportional to the moisture content of the web and is highest at the dry end.

Verso identified a fabric filter collector or baghouse, electrostatic precipitator (ESP), or wet scrubbers and cyclones as possible PM control technologies for PM5. Both fabric filters and ESPs were determined to be technically infeasible. For fabric filters, the presence of moisture in the exhaust stream adversely affects the performance of the filtering media and can contribute to material failures due to corrosion. The former and drying process stack exhaust streams contain significant amounts of

moisture. A search of EPA's RACT/BACT/LAER Clearinghouse (RBLC) did not identify any fabric filter systems used to control PM emissions from papermaking sources. Fabric filter systems or baghouses are not technically feasible to control PM, PM_{10}, and $PM_{2.5}$ emissions from PM5.

The performance of an ESP depends largely on the electrical conductivity of the particles that are being collected, and similar to a fabric filter system, moisture in the gas stream can affect the performance of an ESP. Based on an RBLC search, ESP systems are not currently used to control PM emissions from paper machines. Electrical conductivity and moisture issues make the ESP technology infeasible to control PM, PM_{10}, and $PM_{2.5}$ emissions from PM5.

A wet scrubber or cyclone could potentially be used to control PM emissions from PM5. A search of the RBLC indicates that such systems are employed at a limited number of mills across the country. For Verso's application, the emission rate of particulate matter from PM5 does not support the application of wet scrubbing or cyclone add-on controls. The installation and operation of a wet scrubber or cyclone, as well as the additional ductwork to connect the multiple emission points, would not be economically feasible for this project.

Since none of the add-on PM emission control technologies are justified according to BACT determination criteria for PM5, BACT for $PM/PM_{10}/PM_{2.5}$ for PM5 shall be good operating practices. Good operating practices for PM5 includes measures such as operating and maintaining the unit in accordance with manufacturer's recommendations.

2. Volatile Organic Compounds (VOC)

Paper machines can potentially emit VOC from several operations within the paper machine itself. VOC can be emitted from the addition of VOC-containing chemical additives to the paper forming process. Additionally, other VOC, primarily methanol, are carried over from the pulp manufacturing process in the paper machine whitewater and can be released during paper forming. Verso identified VOC limits on raw materials, adsorption, biofiltration, thermal oxidation, good operating practices, and use of market pulp as possible VOC control strategies for PM5.

The majority of VOC emissions from Verso's paper machines result from methanol and other trace amounts of HAPs carried over in the pulp. The additives that will be used to form the paper products sheet on the paper machine contain inherently low-to-no VOC and will collectively contribute little to the VOC emissions from the paper machine. The additives used at Verso are carefully selected and optimized specifically for the mill's products. Since Verso must carefully select the additives used by PM5, the approach for taking mandated VOC limits on raw materials is not

considered technically feasible as it could negatively impact the characteristics and quality of the final product.

Adsorption of VOC from the paper making process onto an activated carbon bed would be impeded by the moisture and PM/PM_{10} content of the gas stream. The moisture and PM/PM_{10} would clog the pores of the activated carbon and reduce the VOC removal efficiency. PM controls would be required prior to implementing a carbon adsorption control technology, which would be both technically challenging and cost prohibitive for the reasons already outlined. Therefore, adsorption is considered technically infeasible as a control of VOC emissions from PM5.

Biofiltration has no known applications on paper machine emissions in the pulp and paper industry and is typically used for odor control. This technology takes a substantial amount of space and, due to the layout of PM5, a biofiltration system would be too large to install. In addition, the presence of PM in the PM5 exhaust stream could impact the performance of the biofilter medium. For these reasons, biofiltration is considered to be a technically infeasible control technology for VOC emissions from PM5.

The remaining technically feasible control options have been ranked by control effectiveness in the below table:

Control Technology Option	Control Efficiency	Ranking
Thermal Oxidation	95-99%	1
Good Operating Practices	Varies	2
Use of Market Pulp	Varies	3

Verso conservatively estimates that the equipment and installation cost of a regenerative thermal oxidizer (RTO) to be $33,950,000. Assuming a 10-year life expectancy for the RTO at a 7% interest rate, the annual capital recovery cost amounts to approximately $4,800,000. Without including any of the additional costs associated with operating the RTO, the cost effectiveness for controlling 99% of the projected 8.83 tpy of VOC from PM5 amounts to over $543,600 per ton. The cost effectiveness of an RTO is well above that which would be considered economically feasible.

Verso currently uses good operating practices for PM5. Good operating practices for PM5 includes preventative maintenance on all of the associated PM5 equipment and systems, and maintaining records of production and purchasing records of the additives used on the paper machine. Verso does not anticipate any additional economic, environmental, and energy impacts associated with this control technique.

Using purchased market pulp can potentially lower VOC emissions if there is less methanol and other VOC in the purchased pulp than in the pulp that is produced by Verso. However, there is no guarantee that the VOC content will be lower. It is also not economically feasible or environmentally beneficial for Verso to purchase market pulp and ship it to the mill in the quantities that are needed for PM5 production rates.

Verso has proposed that BACT for VOC emissions from PM5 is good operating practices to minimize VOC emissions. Good operating practices include regularly scheduled preventative maintenance on all of the associated PM5 equipment and systems and maintenance of purchasing records of the additives used on the paper machine.

C. Incorporation Into the Part 70 Air Emission License

The requirements in this 06-096 C.M.R. ch. 115 New Source Review license shall apply to the facility upon issuance. Per *Part 70 Air Emission License Regulations*, 06-096 C.M.R. ch. 140 § 1(C)(8), for a modification at the facility that has undergone NSR requirements or been processed through 06-096 C.M.R. ch. 115, the source must apply for an amendment to their Part 70 license within one year of commencing the proposed operations, as provided in 40 C.F.R. Part 70.5.

D. Annual Emissions

No changes to Verso's licensed annual emissions are occurring as a result of this NSR license.

III. AMBIENT AIR QUALITY ANALYSIS

Verso previously submitted an ambient air quality analysis demonstrating that emissions from the facility, in conjunction with all other sources, do not violate ambient air quality standards. NO_2 modeling was conducted in association with air emission license A-203-77-13-A (January 19, 2012), and SO_2, PM_{10}, and CO modeling was conducted in association with air emission license A-203-71-E-R (September 3, 1996). An additional ambient air quality analysis is not required for this NSR license.

ORDER

Based on the above Findings and subject to conditions listed below, the Department concludes that the emissions from this source:

- will receive Best Practical Treatment,
- will not violate applicable emission standards,
- will not violate applicable ambient air quality standards in conjunction with emissions from other sources.

The Department hereby grants New Source Review License A-203-77-25-A pursuant to the preconstruction licensing requirements of 06-096 C.M.R. ch. 115 and subject to the specific conditions below.

Severability. The invalidity or unenforceability of any provision of this License or part thereof shall not affect the remainder of the provision or any other provisions. This License shall be construed and enforced in all respects as if such invalid or unenforceable provision or part thereof had been omitted.

SPECIFIC CONDITIONS

(1) Verso is authorized to complete the PM5 project as described in this NSR license.

(2) Verso shall submit an application to incorporate this NSR license into the facility's Part 70 air emission license no later than 12 months from commencement of the requested operation. [06-096 C.M.R. ch. 140 § 1(C)(8)]

DONE AND DATED IN AUGUSTA, MAINE THIS 11 DAY OF April, 2019.

DEPARTMENT OF ENVIRONMENTAL PROTECTION

BY: Marc Allen Robert Cesa for
GERALD D. REID, COMMISSIONER
