TO: Board of Pesticides Control Members  
From: Mary Tomlinson, Pesticides Registrar/Water Quality Specialist  
RE: Gulf of Maine Coastal Pesticide Study Update for 2015  
Date: January 3, 2017 (Revised memo of Dec. 16, 2016)

In February 2014, the Environmental Risk Advisory Committee (ERAC) was convened to “examine whether current pesticide residues have the potential to affect the lobster industry in Maine directly or via impact on other marine organisms.” Maine’s Joint Standing Committee on Agriculture, Conservation and Forestry, in a letter to the BPC, supported the formation and purpose of the ERAC and requested reports in January 2015 and January 2017. Stormwater and sediment sampling were scheduled for 2014 and 2015. Due to laboratory contract issues and lack of significant rain storms, only sediment sampling occurred in 2014. Results from the 2014 sampling season were reported in the 2015 ERAC Report to the Legislature. Monitoring for the 2015 sampling season was completed in October 2015.

Based on the 2014 sediment sampling results, characteristics of juvenile lobster behavior and habitat, and resource constraints, the Environmental Risk Advisory Committee narrowed the focus to the Casco Bay region. Sediments were collected in 2015 from 13 intertidal sites in Casco Bay. One site on the Saco River, below Biddeford, was sampled to follow up a cypermethrin detection at that location in 2014. Sediment sample sites included previously identified and potential juvenile lobster habitats where fine-grained sediments intersected with cobble at low tide. Two sites with the highest bifenthrin detections in 2014 were sampled for temporal variability.

Sediment samples were analyzed for 21 pyrethroids, piperonyl butoxide (PBO), and methoprene. Montana Analytical Laboratory analyzed for 14 pyrethroids and piperonyl butoxide (PBO). Southwest Research Institute (SwRI) analyzed for 19 pyrethroids, piperonyl butoxide (PBO), and methoprene. Samples were also sent to the University of Maine Analytical Laboratory for analysis of total organic carbon and particle size. Results of the 2015 sediment sampling were received late 2015.

Montana Analytical Laboratory reported detections of bifenthrin in sediment at seven sites and esfenvalerate at one site; Southwest Research Institute reported bifenthrin detections at four sites (Table 1). Sediment samples were collected at two urban sites from April through October. Bifenthrin was detected in every sample at both of these sites. Montana results are reported in wet weight and SwRI results are reported in dry weight. Results cannot be compared among samples or sites until all results are converted to dry weight and normalized for organic carbon. Results can only be interpreted as detections at a single point in time. There were no detections in sediments collected from sites previously identified as juvenile lobster habitat or adjacent to lobster habitat. EPA aquatic life benchmarks are not applicable to sediments.

Stormwater sampling was conducted at 19 sites from Kittery to Whiting over one storm event in August 2015 and at one site in Ellsworth in September. The sample from Ellsworth was overlooked by the Southwest Research Institute (SwRI) and was not analyzed; therefore, only 19 sites were analyzed for pyrethroids, methoprene, and fipronil degradates. The Montana universal method does not include pyrethroids, methoprene, or the fipronil degradates and the detection limit for fipronil is parts per billion compared to parts per trillion used by SwRI. Please refer to the attached analyte lists.
Twenty-two pesticides and fipronil degradates were detected in stormwater (Table 2). Fipronil, imidacloprid, and bifenthrin were the most frequently detected pesticides. Detection frequencies of fipronil degradates were similar to that of the parent compound. Results for fipronil and its degradates were detected in the parts per trillion range, but are displayed in Tables 2 and 3 as parts per billion (ppb) for comparison purposes.

One urban site (Portland) was selected for a four-hour time series. Bifenthrin, 2,4-D, fipronil, fipronil desulfynyl, fipronil sulfone, imidacloprid, and MCPP were detected every hour; fipronil sulfide the first three hours; and imazapyr, triclopyr, and cis/trans-permethrin the first two hours.

The number of pesticides detected in each community in descending order are: Portland (14); South Portland and Rockland (9); Biddeford (8); Kittery and Belfast (7); Boothbay Harbor (6); Ogunquit, Freeport, Bath, Camden (5); Yarmouth and Brunswick (4); Blue Hill (2); Ellsworth (1); Cherryfield and Columbia Falls (2); and Jonesboro, Machias, and Whiting (1).

Bifenthrin and cis/trans-permethrin totaled were the only pesticides detected that exceeded EPA aquatic life benchmarks (ALB) (Table 3). Cis-permethrin and trans-permethrin concentrations were totaled for each sample to obtain the total permethrin concentration for comparison with the ALB. Bifenthrin exceeded one ALB at seven sites and three samples at the Portland time-series site. Permethrin exceeded two ALBs in two samples at the Portland site.
Table 1 Pesticide residue concentrations in sediment, collected in 13 intertidal sites in Casco Bay and one Saco River site, April through October 2015.
