Infectious Disease Epidemiology Report

Legionellosis Maine, 2014

Background
Legionellosis is an illness caused by a type of bacteria called *Legionella*. Legionellosis was first identified in 1976 when attendees at an American Legion convention in Philadelphia suffered from an outbreak of this disease. Legionellosis is spread when people breathe in small droplets of water in the air that are contaminated with the bacteria. The bacteria are not spread from person to person.

Legionellosis is associated with two clinically and epidemiologically distinct illnesses: Legionnaires’ disease, which is characterized by fever, myalgia, cough, and clinical or radiographic pneumonia; and Pontiac fever, a milder illness without pneumonia.

Outbreaks of legionellosis can occur when there is a contaminated water source that is aerosolized, such as at a pool or spa, hospital, or with an air conditioner.

Methods
Legionellosis is a reportable disease in Maine. Maine CDC investigates all reports of disease and completes standardized case report forms. Risk factor information on travel history, spa use, respiratory therapy exposures, and potential healthcare exposures is collected.

*Legionella* is most often confirmed by urine antigen tests, but can also be confirmed by culture or seroconversion (fourfold or greater rise in specific serum antibody titer). The most common serogroup in the United States is *L. pneumophila* serogroup 1, and this is the only serogroup the urine antigen test detects. Other serogroups can be identified by culture or specific serology.

Results
A total of 19 confirmed cases of legionellosis were reported in 2014, a decrease from 23 in 2013 (Figure 1). All 2014 cases were sporadic and no outbreaks were identified.

The rate of legionellosis in Maine in 2014 was 1.4 cases per 100,000 population (Figure 2). The majority of legionellosis cases occurred among males (74%). The median age of cases was 60 years (range 45-80 years).

Eighteen cases were clinically diagnosed as Legionnaires’ disease, one was clinically diagnosed as Pontiac fever. All cases were hospitalized as a result of their infection and two (10.5%) died. Laboratory findings classified 18 cases as *L. pneumophila* serogroup-1 by urine antigen and one case as *L. pneumophila* by culture.

Seven (37%) of 19 legionellosis cases reported staying overnight away from home in the two weeks before onset of symptoms. Four cases met the
Legionellosis – Maine, 2014

Legionellosis was identified among residents of seven Maine counties in 2014 (Figure 3).

Discussion

Legionellosis cases dropped slightly in 2014 in Maine, although the overall trend is still increasing. The reasons for the increase are unknown: some explanations may include increased community exposures and increased usage of air conditioners.

Because legionellosis can be very serious and can also be treated successfully with antibiotics, early identification of infections will improve patient outcomes.

Some people may be at greater risk for legionellosis including:

- People older than 50 years
- Current or former smokers
- People with chronic lung disease (e.g. emphysema)
- People with a weak immune system due to underlying conditions or drug therapy
- People with recent travel with an overnight stay outside the home
- People with exposure to whirlpool spas
- People with recent repairs or maintenance work on domestic plumbing

All cases of legionellosis in Maine must be reported by calling 1-800-821-5821 or by faxing reports to 1-800-293-7534.
