### **Babsons Bridge over Meadow Brook, Route 198, Bridge # 5244**

**Executive Summary:** Bridge #5244 conveys flow from the Meadow Brook under Route 198 in Mount Desert, Maine. The outlet is a tidal stream connected to Somes Sound. The existing bridge is an approximately 20' Single Span Cast in Place Concrete Slab Superstructure on concrete and stacked granite abutments, with a maximum span of 21'. The proposed structure is planned to be a 56' span with riprap on the abutments to support widening.

**Summary Hydrology:** This bridge conveys flow from the upstream drainage basin under Route 198 and is subject to daily and storm tide inundation. The bottom of the bridge channel is higher than low tide. The bottom chord is close to FEMA's 100-year storm surge elevation. Sea Level Rise of up to 4' could inundate the low chord during storm tides, and could overtop the existing bridge assuming current estimates of potential rise for 100-years. Table 1 summarizes project hydrology and tidal elevations.

**Summary Table 1.** Hydrology Summary for Plans

**Summary Hydraulics:** Hydraulic model HECRAS was run in both steady and unsteady flow modes to simulate flow through this bridge which conveys daily and storm tides inland and upland flows seaward. Existing and proposed bridges were modeled, with geometric changes in the bridge deck, in the width of the bridge and in the embankments built to support the widened bridge.

Model combinations include:

| <u>Model Type</u> | <u>Tide Level</u>    | <u>Upland Flow</u>               |
|-------------------|----------------------|----------------------------------|
| Steady Flow       | MHW                  | Q1.1-, Q10, Q25, Q50, Q100, Q500 |
| Steady Flow       | MHW + 4' SLR         | same                             |
| Steady Flow       | MLW                  | same                             |
| Unsteady Flow     | DOT Calibration data | 20 cfs (typical flow)            |
| Unsteady Flow     | MHW                  | 1.1-year                         |
| Unsteady Flow     | MHW plus 4'          | 1.1-year, 10-year                |
| Unsteady Flow     | 50-year surge tide   | 1.1-year                         |
| Unsteady Flow     | 100-year surge tide  | 1.1-year                         |

Modeling and onsite measurements by MaineDOT indicate that the bridge slightly restricts tidal and upland flows with the following notes:

- MaineDOT noted that a goal of the bridge reconstruction is to simulate existing conditions as closely as possible.
- Survey data within the bridge itself was difficult to obtain, but reasonable detail was gathered by MaineDOT for final design. Debris in the channel from what appears to be an old dam at the bridge likely impacts flow in the bridge.
- Under existing conditions, during a typical tide cycle, dataloggers recorded a difference of about 0.2' and about a 30 minute lag in peak elevations.
- Once the additional survey gathered for final design was added to the HECRAS model, the model reasonably simulated existing condition flow when compared to MaineDOT's measured water levels.
- The HECRAS model calibration to DOT recorded data did provide a good simulation of peak water levels and a reasonable simulation of difference in water level from downstream to upstream.
- The HECRAS model provides a good simulation when comparing existing and proposed bridge water levels.
- At maximum normal tide height, with high upland flows, the upstream level is very slightly higher than downstream for the existing bridge, but levels are projected to equilibrate for the proposed bridge.

- Modeling indicates that nearly full tidal surge levels are propagated upstream during storm tide events under existing conditions and the proposed bridge is likely to propagate the full 100-year surge.
- The existing bridge does not meet MaineDOT tidal bridge standards for clearance, using upland Q10 and MHW tide plus 4' with 0.3-0.6' of clearance.
- The proposed bridge will provide 1.4' to 1.9' of clearance across the bridge section using Q10 at MHW plus 4' SLR. MaineDOT recommends 2' of clearance but also includes engineering judgement based on the specifics of the project site.
- The proposed bridge will convey the upland 50-year flow against MHW plus 4' SLR with the same clearance as the 10-year upland flow.

Hydraulic data is summarized in Summary Table 2.

**Summary Table 2.** Hydraulic Summary for Plans

## Introduction:

This report details work related to hydrologic, hydraulic and scour analysis at Babsons Bridge, Route 198, over Meadow Brook in Somesville/Mount Desert, Bridge #5244. The project site is shown in Figure 1.

**Figure 1:** Site Location Route 198 over Meadow Brook #5244.

Babsons Bridge crosses over Meadow Brook, which collects limited amounts of upland runoff and cycles with the tides each day. The bridge site is protected from large ocean waves due to its location at the most inland point of Somes Sound. Figure 2 shows a closeup aerial view of the bridge location.

**Figure 2:** Aerial Photo, Meadow Brook, Somesville/Mt Desert.

According to inspection reports, the existing bridge consists of a 21' structure length, concrete cast-in-place slab on stone masonry abutments with stone retaining walls. The superstructure of the original bridge was replaced in 1949. The original date of construction of the abutments is unknown. The bridge was reconstructed again in 1977. The 2017 inspection report describes both abutments as having minor to moderate voids throughout and findings of undermining where voids occur, but that abutments appeared to be stable. The bridge has not been evaluated for scour. The 2017 inspection report notes occasional overtopping of approaches. Current notes in the Maine Bridge Database as of July 2019 show the bridge to be in a state of advanced deterioration. Bank slumping causing minor damage was also noted. The upstream face of the bridge is shown in Figure 3.

**Figure 3.** Upstream face of bridge near high tide. Utility line is lower than existing low chord.

**Figure 4.** Looking downstream from bridge at low tide.

**Figure 5.** Downstream face of bridge, outgoing tide near mid-tide.

**Figure 6.** Looking upstream from bridge.

In addition to upland flows, this bridge site is subject to flows in both directions due to tidal influx. A goal of the hydraulic analysis is to determine whether this bridge restricts the amount of tidal waters that can travel upstream and fill the basin above the bridge, or whether the bridge allows for the full tidal cycle to fill the pond upstream of the bridge.

Goals for hydrologic and hydraulic design included:

- Evaluate potential flood elevations for bridge profile design based on tidal and upland flood analyses.
- Evaluate up- and down-stream water levels under a variety of tide/streamflow conditions.
- Evaluate rate of flow through bridge under normal and flood tides and due to freshwater flows
- Evaluate whether the bridge restricts flows either from the tidal side to upstream or from the watershed flowing downstream.
- Evaluate scour potential based on predicted and measured velocity, observed bed material and bridge geometry

MaineDOT offers the following relevant guidelines in Chapter 2 of the Bridge Design Guide for bridge design clearance and freeboard:

Riverine:

- All bridges should be designed to safely convey Q50

Tidal Structures:

- Bridges – Design to protect the structure

- Minimum Design Freeboard “2 feet above Q10 (based on MHW) including wave heights”.

### Sea Level Rise:

This report considers sea level rise of up to 4’ for the project. The May 2018 update to Maine DOT’s Bridge Design Guide includes the following:

#### “2.3.7 Changes in Sea Level

*Historical data from NOAA shows that the sea level along the Maine coast over the past 80-100 years has risen between 0.5 and 0.75 feet per 100 years relative to local datums. More detailed information is available from the NOAA Tides and Currents website in the Sea Level Trends section. Based on this historical data and NOAA projections, the proposed design should assume 4 feet of sea level rise per 100 years.”*

MaineDOT’s Bridge Design Guide recommends the following for tidal bridges:

*“Bridges in tidal area - Bridges on tidal rivers/streams should be designed to protect the bridge structure itself. Most of the surrounding land and the approach roadways may be inundated by relatively frequent tidal storm surges. The minimum design freeboard in these areas is 2 feet above Q10 (based on MHW with sea level rise), including wave heights.” (pages 2-31)*

MaineDOT recently provided updated guidance on Sea Level Rise with a graphic showing potential sea level rise scenarios, Figure 7. The “Intermediate or I” trend projects 4’ by 2100.

Figure 7: Sea Level Rise Projections for Portland (From NOAA Sea Level Rise Viewer)

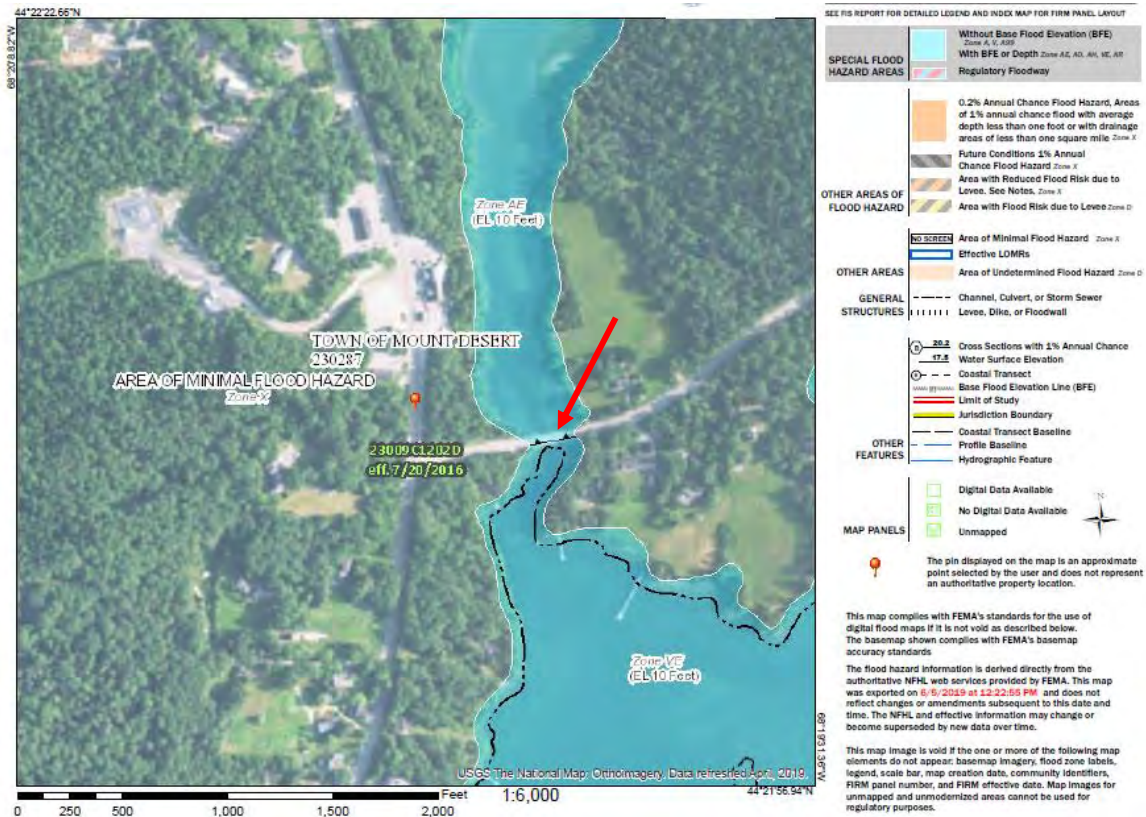

Additional DOT guidance includes: The finished grade of the bridge will be set by considering this requirement, along with navigation clearance, the approach roadways, topography, and good engineering judgment.

## **2.0 Review of Existing Data and Site Visit:**

Existing information was gathered and reviewed. Data included:

- FEMA Flood Insurance Studies of Mount Desert, including LOMR/LOMA map revisions. Figure 8 shows the Effective FIS map for the bridge area, with a zone designation of VE 10 feet on the downstream side of the bridge and AE 10 feet upstream of the bridge. The map is based on updated FEMA analysis published in July of 2016.
- NOAA tide data and coastal charts, Figure 9.
- MaineDOT file information:
  1. Babsons Bridge, Plans. May 1949. 21 foot width plank roadway with 5 foot sidewalk.
  2. MaineDOT Correspondence 1948 – 1977: Note that this correspondence describes a fire detention dam in the bridge and an oyster farming dam upstream of the bridge.
  3. Inspection report notes: 2011, 2014, 2014, 2015, and 2017.
- Air photos
- Topographic Maps
- Historical Flood Information
- NOAA Tide gage data: NOAA publishes predicted tide data for several stations near the site, including at the opening to Somes Sound and the recording station # 8413320 at Bar Harbor (Figure 10).

**Figure 8.** FEMA map panel for Mount Desert at the project site (red arrow).

**Figure 9.** NOAA Chart 13318 near project site. Note that water depths do not extend up to site (red arrow). All depths are shown as MLLW datum, used for navigation (0' MLLW = -5.95' NAVD).

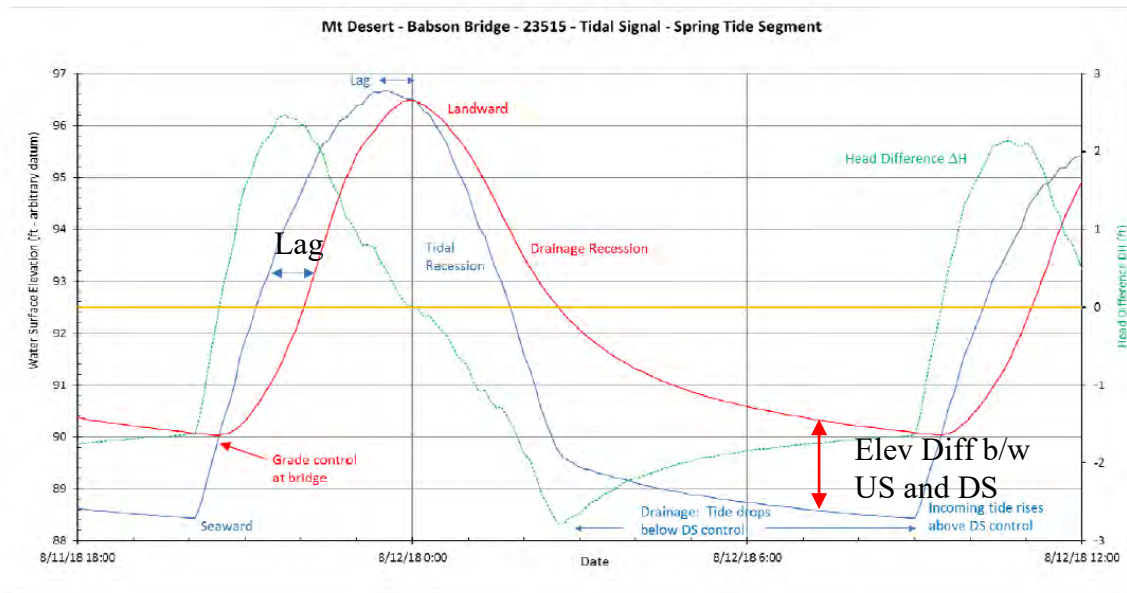

**Figure 10:** NOAA Tide Prediction Stations (white pins) and Recording Station at Bar Harbor (blue pin), bridge site shown by red arrow.

A table in the appendix summarizes available tidal datum information. Project tidal hydrology is summarized in section 3.0 of this report.

## 2.1 MaineDOT Tidal Measurements:

MaineDOT conducted tide measurements using pressure transducers and data loggers from July 11 through August 23, 2018. The internal memorandum from Charles Hebson on November 16, 2018 titled *23515 Mt Desert – Babson Bridge #5244 – Tidal Hydrology* summarizes the analysis of their measurements and is included as an appendix to this report. The analysis shows a tidal restriction at the bridge which is caused by grade control within the bridge and may be exacerbated by the bridge opening. Figure 11 shows a 12-hour tide cycle. The plot shows that upstream elevations remain several feet above downstream elevations at low tide due to a grade control within the bridge. The tide cycle also shows a time lag between upstream and downstream elevations above the grade control. This is likely the result of the bridge restricting upland flow. This record shows a difference of a few tenths of a foot from upstream to downstream, and a time lag of about an hour.

**Figure 11:** Rising and falling tide hydrograph at bridge. Note graph shows that the low tide upstream (red curve) of the bridge is several feet higher than downstream (blue curve) of the bridge (red arrow) and there is a lag between the DS and US hydrographs.

## 2.2 NHI Site Visit, Measure water levels and estimate flow velocities:

NHI measured water levels and estimated flow velocities over a portion of a falling tide cycle to determine how the bridge interacts with the complex flows generated by combined tides and upland flows. Tidal elevation and flow data were gathered at the site over an ebbing tide starting at peak tide level. Up- and down-stream elevations at the bridge were measured at selected intervals. Measurements were taken on March 20, 2019 from 10:41 am to 1:09 pm. Measurements were taken from top of rail of bridge at each abutment as well as at center-bridge, at both up- and down-stream faces. High tide for that day was predicted to occur at Station # 8413564 (Southwest Harbor) at 10:49 am. At the project site, the tide continued to flow upstream until 10:55 am. Predicted high tide was 6.50' NAVD and predicted low tide was predicted -7.47' at 4:42 pm.

**Figure 12.** Example tide measurement location from top of rail at DS Right Abutment (red X).

The bridge was surveyed in 2019. Field measurements of the rail, fascia, and beam depths were made, and combined with survey data to determine the existing top of rail and associated bottom chord elevations. Table 2 lists computed bridge elevations.

| Location Along Bridge | Side of Bridge | Top of Rail Elevation (ft) | Bottom Chord Elevation (ft) |
|-----------------------|----------------|----------------------------|-----------------------------|
| East End              | North (US-L)   | 15.21                      | 9.69                        |
|                       | South (DS-L)   | 14.98                      | 9.28                        |
| West End              | North (US-R)   | 15.16                      | 9.67                        |
|                       | South (DS-L)   | 15.10                      | 9.57                        |

**Table 1.** Bridge rail elevations, US – upstream, DS – downstream L – left, and R - right.

Field measured water levels, velocities and calculations are included in the appendix. Tide elevation values calculated from measured data combined with bridge survey data ranged from 6.5 to 2.1 feet NAVD on the downstream side of the bridge. Field data are graphed in Section 5.0 of this report on hydraulic analysis and modeling.

### 2.3 Velocity Estimates:

To assist in calibration of the hydraulic model, tidal flow velocities were estimated by tossing and timing a thrown object as it passed through the bridge. Each measurement was repeated at least three times and averaged. While this method provides rough

estimates of velocity, previous comparison to flow meter data has been found to be quite close at other project sites.

| Time     | Estimated Velocity, fps | Velocity Head, ft, $V^2/2g$ |
|----------|-------------------------|-----------------------------|
| 11:35 AM | 2.70                    | 0.11                        |
| 11:54 AM | 4.80                    | 0.36                        |
| 12:08 PM | 5.59                    | 0.49                        |
| 12:27 PM | 6.95                    | 0.75                        |
| 12:49 PM | 7.70                    | 0.92                        |
| 1:09 PM  | 8.58                    | 1.14                        |
| 4:30 PM  | 5.21*                   | 0.42*                       |

**Table 2.** Summary of calculated velocity measurements (3/20/19). \* Denotes high levels of turbulence in outflow making velocity measurements difficult to obtain. Flow was likely supercritical.

## 2.4 Predicted Tides on Day of Measurements:

To assist in calibrating the hydraulic model, measured tide data was compared to predicted tide data. Available tide data was analyzed to determine the best data to use for prediction of tide elevations at the project site. Two NOAA tide stations were evaluated, with the final choice being station # 8413564, the Southwest Harbor Station at the inlet of Somes Sound, which is a prediction station rather than recording station. Data for the day of tide measurements is shown below. Bar Harbor is the closest recording tide gage. Southwest Harbor allows tide elevation computations based on the predicted or recorded tides at Bar Harbor. At the project site, the Southwest Harbor predicted tides were adjusted slightly based on recorded tides at Bar Harbor, which were slightly different than predicted.

1. Tides at Station # 8413564, Southwest Harbor, Predicted based on Bar Harbor

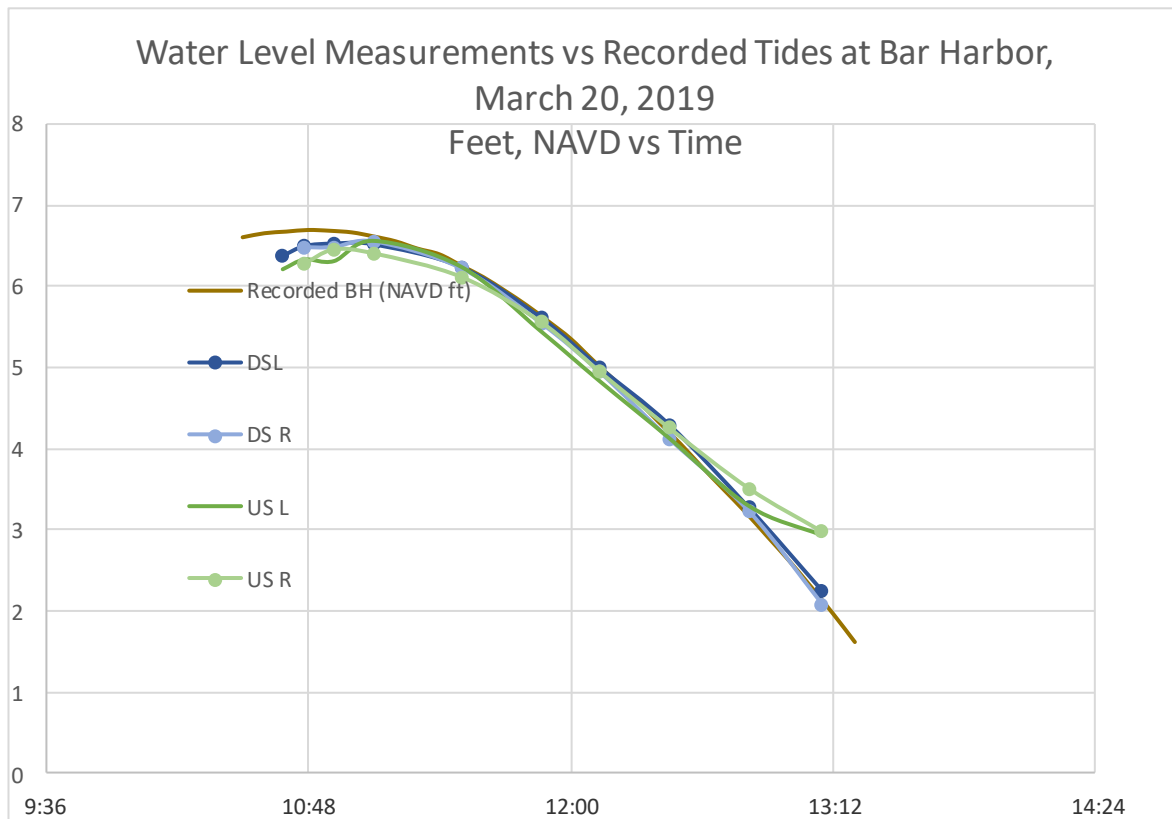

**Figure 13.** Predicted tides at Station 8413564, Southwest Harbor, 3/20/19. Based on Bar Harbor \* 0.96 H, 0.95 L

| Time     | Predicted, at Bar Harbor, ft MLLW/NAVD Station 8413320 | Recorded at Bar Harbor, ft MLLW/NAVD Station 8413320 | Predicted SW Harbor MLLW/NAVD Station 8413564 | SW Harbor based on Bar Harbor Recorded NAVD | Measured at Project Site, Downstream NAVD | Measured at Site, Upstream, NAVD |

**Table 3.** Measured Tides at Project Site vs Predicted Tides 3/20/19  
Bar Harbor Tides Recorded adjusted to Station # 8413564

**Figure 14.** NHI measured water levels at Babson's Bridge vs Recorded at Bar Harbor. Note that peak at site is about 0.1' lower than Bar Harbor and lagged by about 15 minutes.

## 2.5 Site Visit Photographs

Photographs were taken on March 20, 2019.

**Figure 15.** Upstream face mid-falling tide. Note utility line near upstream face of bridge.

**Figure 16:** Looking at west abutment at mid-falling tide, note grade control in channel.

**Figure 17.** Downstream face of bridge, low tide.

**Figure 18.** Downstream of bridge, near low tide.

**Figure 19.** Looking upstream near low tide.

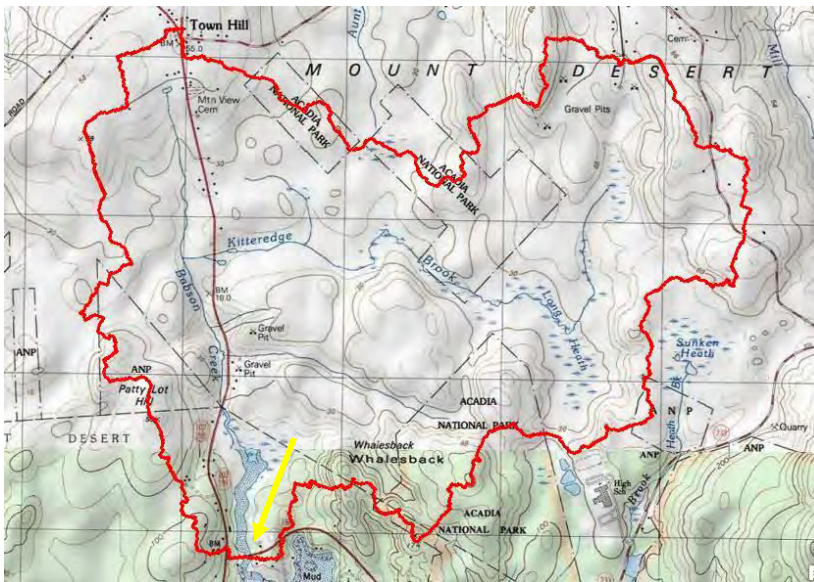

**Figure 20.** Looking through bridge US to DS near low tide.

### 3.0 Hydrologic Analysis:

Tidal and upland hydrology were computed at the project site. Upland hydrology for Meadow Brook was computed by MaineDOT using USGS methodology. Drainage basin and drainage basin characteristics are shown in figure 16.

**Figure 21.** Drainage basin to Babson Bridge (yellow arrow), 3.4 sq. mi. drainage area (red).

| Recurrence Interval | Flow (ft <sup>3</sup> /s) |
|---------------------|---------------------------|
| 1.1                 | 49                        |

**Table 5.** Summary of Tidal Elevations

The following flow/tide combinations were selected as boundary conditions for analysis in the hydraulic model.

**Steady Flow:**

- 1.1-year, 10-year, 25-year, 50-year, 100-year and 500- year Q with MHW
- 1.1-year, 10-year, 25-year, 50-year, 100-year and 500- year Q with MLW
- 1.1-year, 10-year, 25-year, 50-year, 100-year and 500- year Q with MHW+4' Sea Level Rise (SLR)

**Unsteady Flow:**

- Data logger data coupled with estimated upland flow
- Typical daily flow coupled with MHW/MLW
- 10-year upland flow with MHW/MLW
- 10-year upland flow with MHW/MLW plus 4' SLR
- 1-year upland flow coupled with 50-year surge
- 1-year upland flow with 100-year surge

Synthetic storm surge hydrographs for the project site were compiled as follows:

1. A tide curve simulating predicted MHW to MLW tides was generated via spreadsheet.
2. A second tide hydrograph set was created by adding 4' to the MHW-MLW hydrograph to simulate potential sea level rise.
3. MaineDOT provided a suggested method for calculation of storm surge based on a regional ADCIRC model that covered multiple states. These surge levels were then added to the MHW/MLW representative tide cycle to produce simulated 50- and 100-year storm tides.
4. Tide/surge hydrographs were routed through the model as the downstream boundary condition.
5. These surge levels may be compared to the estimated HOWL of 10.24' of February 7, 1978. This is based on the Bar Harbor gage.
6. Velocity estimates were prepared to evaluate potential scour. For tidal systems, fastest velocities occur when tides are changing most rapidly, such as during a surge event and when water levels are low, usually mid-tide. Peak velocities were selected from modeled hydrographs at the proposed bridge at times of highest flow rates.

#### **4.0 Site Survey and Topography**

Project survey was completed by MaineDOT on June 26, 2019 for the bridge, roadway, and bathymetry in the area of the bridge. This survey was merged with a 1-m DEM derived from the 2010 USGS ARRA Lidar for the Northeast: Maine Project for all areas outside of the project survey. For the tidal basin portion of Meadow Brook upstream of the surveyed area, bathymetry was estimated through aerial photography to create an elevation-area relationship used to calculate tidal storage volumes. Bathymetry for the furthest downstream cross sections was developed based on estimates from NOAA Navigational Chart 13318. The elevations were merged to create a terrain surface for the hydraulic model.

For final design, MaineDOT provided additional survey data points under the bridge such that the hydraulic control at the upstream edge of the bridge could be defined in the model.

Survey points are shown in figure 22 below. Points were used to create a best estimate of the control section elevation by selecting critical points within the data and considering MaineDOT's measured water levels from 2018. The selected bridge section is shown in the report section detailing hydraulics and modeling and the report appendix.

**Figure 22.** Survey points in bridge section.

## 5.0 Hydraulic Analysis:

A HECRAS hydraulic model, version 6.0, was prepared for the project site to simulate tidal and upland flow through the existing bridge and the proposed bridge.

The model was calibrated based on MaineDOT datalogger data as described in section 2.1 above. NHI also collected and observed water level changes and rates of flow over part of a dropping tide cycle to assist in calibrating the hydraulic model.

The HECRAS model was compiled in both steady and unsteady flow modes, and uses predicted tides at Bar Harbor for the downstream boundary condition and peak flows as

calculated in section 3.0 above for upland flows. Calibration runs compared downstream model cross section 888 and upstream section 1013 to datalogger data. These sections are also used to report water levels for theoretical storm events.

Bridge geometries include:

- Existing: span of 25', Low Chord 9.3 to 9.8' downstream and 9.7' upstream. Span at channel base is approximately 15' with base elevations upstream of about 0.5' and downstream face of -1.0'.
- Proposed: span of 56', low chord of 10.4' to 10.9', and a road profile at 14.1 to 14.7' at the abutments. Base of channel to be same as existing bridge, with riprap abutment protection sloping from the new abutments to the channel base to maintain same base width.

Goals of the hydraulic analysis include:

- Assessment of flood elevations for existing and proposed bridges
- Flow velocity studies for scour analyses under existing and proposed conditions.
- Understanding of interaction of tides, upland flows and bridge structure.

Figure 23 shows the geometric model layout with cross sections shown in green, storage area shown in blue, and channel banks in red.

**Figure 23.** Full hydraulic model layout with upstream tidal basin (approximate boundary shown).

**Figure 24:** Hydraulic model layout in bridge area

**Figure 25.** Model contours (1 ft interval) .

Initial model runs were performed using data collected by MaineDOT at the project site using installed data loggers, as described above. Downstream data logger elevations were used for the boundary condition in the hydraulic model, and an assumed low upland flow of 6 cfs was used for the upstream boundary condition. Median flows for these months are predicted to be about 0.2 to 0.5 cfs. However, the unsteady flow model was unstable with flows lower than about 6 cfs. The model was run for the full data set that runs from July 11 to August 23, 2018.

Figure 26 shows calibration data plotted against modeled data for existing conditions at model locations that were representative of the data logger locations. The figure shows datalogger data at up- and down-stream locations, model data, and elevation differences from up- to down-stream for both conditions.

**Figure 26:** MaineDOT measured water levels plotted against HECRAS model data, water levels and water level change from up- to down-stream.

Figures 27, and 28 show model results for the full model profile, and section through the existing bridge with typical conditions of upland flow and MHW-MLW tide range.

**Figure 27.** Existing Bridge model profile, left side is downstream, right side is upstream. This figure shows variation in water levels over a MHW to MLW cycle with minimal upland flow.

**Figure 27.** Existing bridge, hydraulic control point, upstream, Tide levels MHW to MLW plus typical upland flow. Upstream face. Channel bottom at hydraulic control point is based on recent survey by MaineDOT.

The proposed bridge is a 56' single span on concrete abutments with riprap protection sloping to the existing bed with a base width of approximately 20'. The proposed bridge section as modeled in HECRAS is shown in figure 28.

**Figure 28.** Proposed bridge plotted Left to Right facing downstream. MHW to MLW plus typical upland flow.

Hydraulic data is summarized in Table 6 below.

**Table 6.** Summary of Hydraulic Results

Table 7 on the following page summarizes results of the steady flow models. Table 8 summarizes unsteady flow results.

#### **Wave Action:**

The project site was reviewed for potential wave action and is found not likely to experience significant waves using USACOE methodology. However, the FEMA FIS lists the downstream side of the bridge as a zone VE, meaning potential wave action greater than 3 feet.

**Table 8. Final Design Unsteady Flow Results, Existing and Proposed**

## Utilities:

Just upstream of the bridge, a utility line crosses the stream at a lower level than the low chord of the existing bridge as shown in figure 29.

**Figure 29. Utility line just upstream of existing bridge.**

The bridge low chord is 9.3 to 9.6'. MHW tide plus 4' of sea level rise with Q10 upland flow is predicted to be 9.0' under existing and proposed conditions. 100-year surge is predicted to be 9.2', all putting the utility line at risk for inundation during storm events. Such events carry the risk of rapidly flowing water in both directions over time, as well as submergence.

## Summary of Significant Hydraulic Findings:

- Under current conditions, water levels upstream of Babsons Bridge are affected by structures near and in the bridge designed to pond water for firefighting and other goals.
- These structures were surveyed in as much detail as the site allowed, with some data interpretation required to compile the geometric model.
- MaineDOT indicated that a goal for the replacement bridge is to maintain the current water level regime for typical tides and for storm tides.
- The final HECRAS model showed good calibration to MaineDOT measured tide data upstream of the bridge.
- Under existing conditions, during typical daily tides, incoming high tide levels nearly equilibrate from downstream to upstream. Data loggers show a slight lag

in time from downstream to upstream peak tide, and a small drop in elevation from downstream to upstream peak tide.

- Low tide levels are controlled by the structures near the bridge and by the bridge abutments, and do not drop below about 0.8'.
- Upstream water levels due to high upland flows are predicted to be lower with the proposed bridge than with the existing bridge. The 100-year upland flood combined with MHW would be about 0.3' lower under proposed conditions.
- Velocities are predicted to be lower with the proposed bridge, although rapid flow is still predicted during times of low tide levels due to the steep channel base under and downstream of the bridge.
- The 100-year storm surge peak level upstream of the bridge is predicted to be slightly higher (0.1') under proposed conditions than under existing conditions.
- The 10-year storm against MHW plus 4' of SLR shows 0.3-0.6' of clearance under existing conditions and 1.4' to 1.9' of clearance with the proposed bridge.
- Clearance for the 50-year tidal surge is the same as the 10-year upland storm with MHW plus 4' SLR.
- The existing utility line is lower than the bridge low chord, which is slightly higher than the 50- year storm surge or high tide with potential 100-year sea level rise.

## 6.0 Scour Considerations:

Scour at the proposed bridge would be limited to contraction and long term bed scour. Abutments are to be protected with riprap. Bed material size distribution is based on the following sieve analyses from borings.

| Boring Number | Depth of Sample | D50    | D84   |
|---------------|-----------------|--------|-------|
| B 101         | 15-17'          | 1 mm   | 20 mm |
| BB 101        | 26-28'          | .18 mm | 5 mm  |
| BB 102        | 1-3'            | 1 mm   | 12 mm |
| BB 102        | 15-17'          | 1 mm   | 20 mm |

Contraction scour was computed using methods recommended in FHWA HEC-18. The following table summarizes contraction scour computations, with general contraction scour ranging from 4-5' if bed material is exposed at the channel bed surface.

Contraction scour would likely be limited by the large rocks and other debris within the bridge channel. However, scour was computed under worst case potential conditions, assuming no channel bed protection.

**Figure 30.** Photo looking upstream into the bridge showing bed protection. This protection only extends across the existing channel.

No information was found related to long term bed scour.

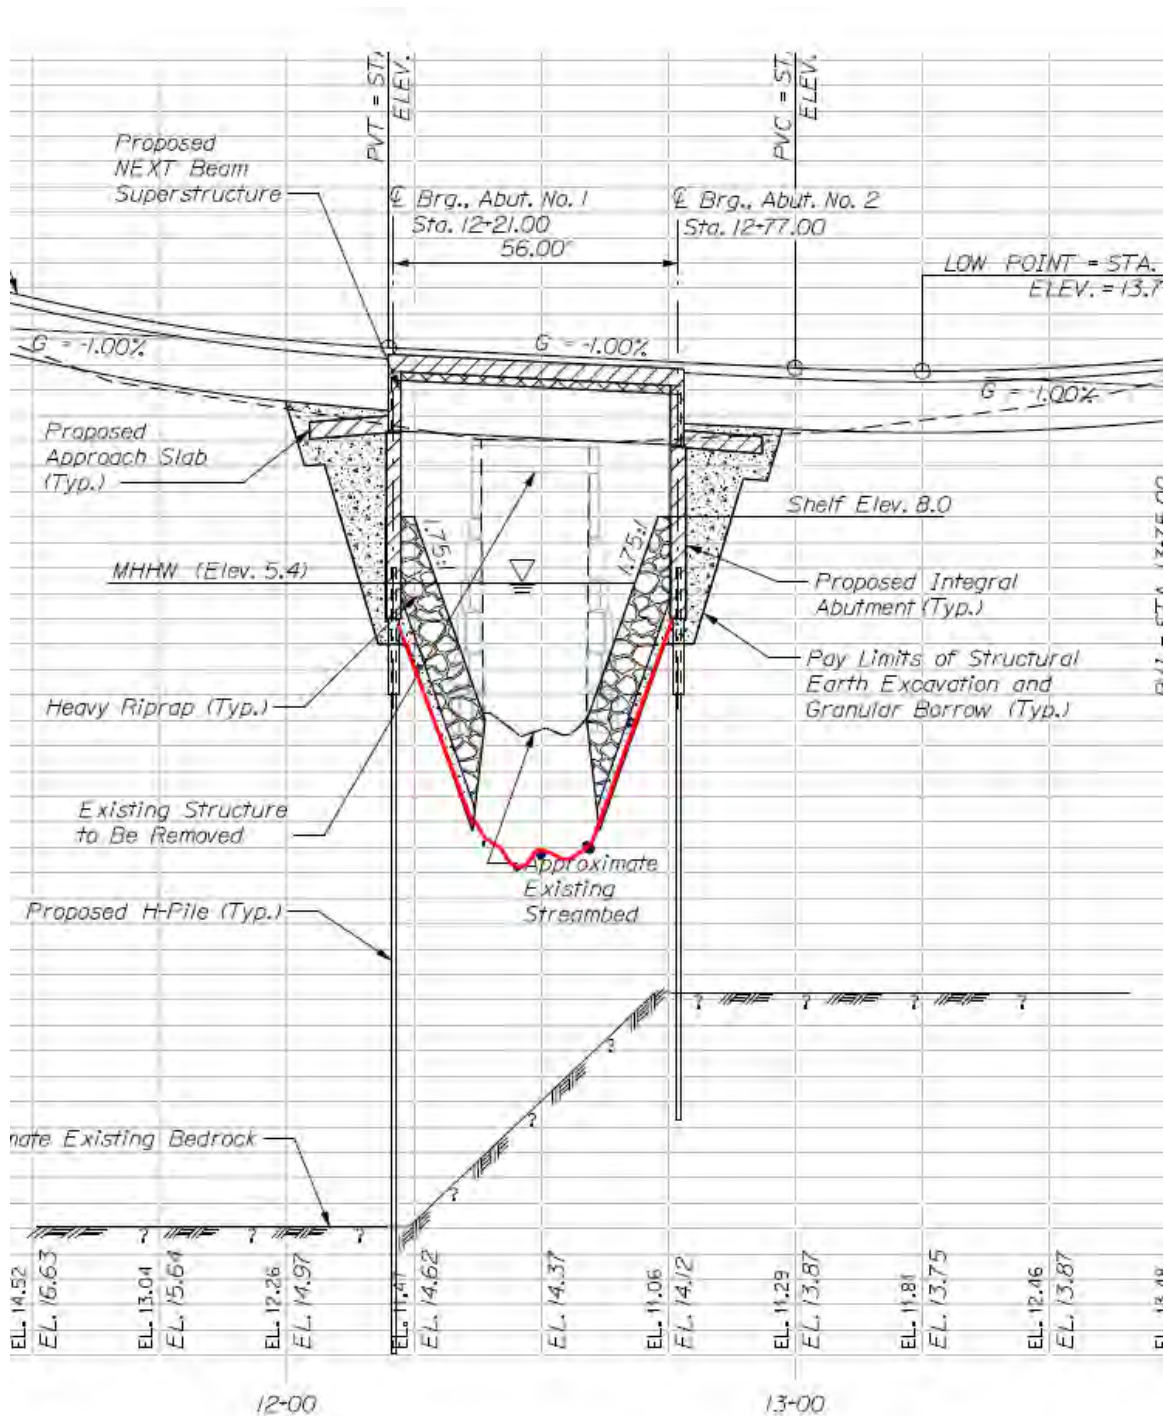

Predicted scour depths are shown below assuming no channel protection.

| Model time  | Q, frequency | Tide, frequency | Contraction Scour Depth,<br>feet below bed |
|-------------|--------------|-----------------|--|
| 02 0450     | 10-year      | MHW+4'          | 3.8  |
| 02 2320     | 1.1-year     | 100-year surge  | 5.1  |
| Steady Flow | 500-year     | MLW             | 4.9  |

Scour projections in tidal waters are generally considered conservative. Scour computation methodologies were developed based on riverine flow conditions in one dimension. Storm surges are limited in time, occurring as a long amplitude wave, with both incoming and outgoing components. Daily tides also are long amplitude waves (12 hours from peak to peak) with both incoming and outgoing components that may shift material in either direction.

Project plans indicate that riprap abutment protection for the new bridge will extend to the current channel base width, thus protecting the existing channel bed material. The potential scour prism assuming no bed protection is shown below on the project plan section plot in figure 31.

**Figure 31.** Proposed bridge section with scour prism assuming no channel bed protection. Red line shows predicted scour prism based on 5' of contraction scour and 2:1 side slopes for the scour prism.

### Embankment piping:

During Northstar's field visit, it was noted that water appeared to flow through the roadway embankment on the westerly downstream embankment beyond the riprap that shows in figure 31 below. A close-up of the area of piping is shown in figures 32 and 33.

**Figure 32.** Westerly downstream embankment location of piping (red arrow)

**Figure 33.** Areas of active piping through embankment, flow from downstream to upstream on incoming tide.

Re: 23515 Mt Desert – Babson Bridge #5244 – Tidal Hydrology

---

### Executive Summary

Tidal stage data was collected upstream and downstream of Bridge #5244, Babson Bridge, for the period 11 July – 23 August 2018. The data suggest the presence of a restriction at the bridge. Grade control beneath the bridge surely plays a part in this; the opening of the bridge may also be a factor.

### Discussion

Grade control at the bridge has created a tidal flat-water impoundment upstream labeled as Kittredge Brook on maps. The upstream data logger was placed at a boulder just off the embankment, as shown in Figure 1. The downstream logger was placed in a rock cluster near the east bank, as shown in Figure 2. Figure 3 shows the grade control at the bridge inlet. Approximately 200-ft downstream of the bridge is a second grade control in the channel, shown in Figure 4. At the time of data collection, survey control had not yet been established at the site, so all elevations are to an arbitrary local datum created for this purpose. The datum has been marked and noted, so that it can be converted to NAVD88 in the future once survey control has been set.

Tidal stage is graphed for the August spring tide period in Figure 5A. At peak high tide there is a very small head drop across the bridge,  $\Delta h < 0.2'$  (2.4"). The time lag between peak tides is about 30 minutes; the lag on the rising tide can be as large as 54 minutes. At lower tides (Figure 5B) the difference is smaller to non-existent. The effect of the grade controls is evident in both sets of tides. The upstream falling limb displays the shape typical of reservoir / pond drainage. This may be due to a bridge opening restriction as well as the grade control, since the drainage shape is apparent as soon as the tide turns and even when the downstream tide is still above the elevation control at the bridge. The downstream falling limb follows a typical tidal shape until tide falls below the downstream control elevation.

Figure 6 shows a portion of the spring tide for better illustration. There is a small time lag between downstream peak and upstream peak, with the corresponding small head difference between peaks. At any given instant, there is a noticeably larger head difference over the course of the rising limb once the downstream tide rises above the bridge grade control. This is probably due to a combination of grade control as well as opening restriction. Once the upstream tide turns, the upstream water level is always higher than downstream, again due to the restriction at the bridge; the upstream water level remains higher than downstream until the next incoming tide rises above bridge grade control.
