SUMMARY

Fleet 1, Pine State Trading, is a regional beverage distributor whose fleet conducts last-mile delivery operations of beer, wine, liquor, and non-alcoholic beverages throughout the State of Maine. Pine State Trading's fleet domiciles at sites in Bangor and Gardiner. Their fleet consists of three cargo vans, nine Class 6 trucks, two Class 7 trucks, and 57 Class 8 trucks.

Pine State Trading's fleet travels between 55–130 miles per day and returns to either the Bangor or Gardiner site to domicile for 11 hours overnight. This duty cycle is well-suited to electrification, since the range fits what electric models offer and there is ample time to fully charge overnight. Pine State Trading's Class 7 and Class 8 vehicles would require fast charging (Level 3), while the others can be charged using Level 2 charging.

Total cost of ownership analyses were performed for each vehicle class in Pine State Trading's fleet, across an assumed lifespan of 12 years and taking into account available incentives in addition to purchase, infrastructure, and operational costs. Pine State Trading's cargo vans and Class 6 trucks produced favorable total cost of ownership (TCO) projections, making them excellent near-term candidates for electrification. Their Class 7 and 8 trucks did not produce favorable TCO projections, though incentives got them much closer to reaching cost parity to traditional models. These vehicles are still great longer-term candidates for electrification due to their well-suited duty cycle and use case.

INTRODUCTION

The Maine Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles ("roadmap") charts a path for Maine to decarbonize the trucks and buses moving people and goods within and through the state. As part of the roadmap, the project team has conducted a series of case studies with Maine businesses to identify real world opportunities and challenges for fleet electrification. The case studies are intended to 1) serve the participating fleets by providing customized fleet electrification assessments; and 2) augment the roadmap by evaluating electrification use cases, total cost of ownership, and barriers in the context of actual Maine business operations.

Fleet Information

Pine State Trading has 62 vehicles that are used for last-mile delivery of beer, wine, liquor, and non-alcoholic beverages. Vehicles are housed at two locations: their main warehouse in Gardiner and their cross-docking location in Bangor. Trucks are dispatched for deliveries or product transport from one of these two locations. The vehicles operate beginning at 5:00 a.m. daily and domicile for 11 hours overnight. Table 1 shows an inventory of the fleet.

	Vehicle		Fuel	Manufacturing Year	Average Annual	Owned or Leased
Vehicle Group	Quantity	Vehicle Class	Туре	(average)	Miles	Vehicles
Mack Pinnacle gf\Tractor	13	Class 8—Over 33,000 lbs.	Diesel	2016	28,000	Owned

TABLE 1 FLEET 1 VEHICLE INVENTORY

Vehicle Recommendations

To adequately define the needs of a fleet, the vehicles used are categorized into duty cycles. Duty cycles are classifications that describe both the *vehicle*, by type and class, and *how it is operated*, including typical miles traveled, type of use (local versus highway), and fuel consumption.

Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles Case Study: Fleet 1

Vehicle recommendations are not exhaustive of all options that may be on the market; selections are included based on those most likely to meet Pine State Trading's duty cycles.

GMC Savanna/Ford Transit Van

Pine State Trading operate three Ford Transit or GMC Savanna vans that drive an average of 55 miles per day and dwell for 11 hours overnight. One of these vehicles domiciles at their Bangor Cross Dock and the other two domicile at their Primary Warehouse in Gardiner. All recommendations can meet Pine State's current duty cycle, though the Logistar 300 would require Level 3 charging to do so within its scheduled dwell time. Recommended replacement options are shown in Table 2.

TABLE 2 VAN ELECTRIC REPLACEMENTS

Class 6 Straight Truck

Pine State Trading operate nine Class 6 straight trucks that drive an average of up to 78 miles per day and dwell for 11 hours overnight. Two of these vehicles domicile at their Bangor Cross Dock and the other seven domicile at their Primary Warehouse in Gardiner. All recommendations can meet Pine State's current duty cycle; even though several recommendations' charging times extend past the 11-hour dwell time, the vehicles can likely charge enough in 11 hours to meet the daily mileage needs using Level 2 charging. Recommended replacement options are shown in Table 3.

TABLE 3 CLASS 6 STRAIGHT TRUCK ELECTRIC REPLACEMENTS

Class 7 Straight Truck

Pine State Trading operate two Class 7 straight trucks that drive an average of 59 miles per day and dwell for 11 hours overnight at their Primary Warehouse in Gardiner. Most Class 6 recommendations are also available as a Class 7 build, with the addition of the Kenworth K370E. All recommendations can meet Pine State's current duty cycle using DC fast charging, which is typically used by Class 7 trucks. Table 4 shows recommended replacement options.

Class 8 Trucks

Pine State Trading operate 57 Class 8 trucks that drive an average of up to 130 miles per day and domicile for 11 hours overnight. 15 of these trucks domicile at their Cross Dock in Bangor and 42 domicile at their Primary Warehouse in Gardiner. All recommendations can meet Pine State's current duty cycle using DC fast charging, which is typically used by Class 8 trucks. Table 5 shows recommended replacement options.

TABLE 5 CLASS 8 ELECTRIC TRUCK REPLACEMENTS

CHARGING AND INFRASTRUCTURE

Fleet Electrification Overview

Fleet electrification involves coordination between the fleet and their electric utility, contractors, developers, vehicle original equipment manufacturers, and electric vehicle service providers to determine the power, quantity, and arrangement of electric vehicle supply equipment (EVSE), or vehicle charging, for a particular site. Once vehicle quantity and duty cycles are defined, the quantity and power of EVSE needed can be determined. In most fleet charging configurations, it is typical to install one dedicated charging plug per electric vehicle (EV). This is to support overnight charging, when electricity rates are low and vehicles are ordinarily not in operation; overnight charging typically lends itself to less costly EVSE due to the lower power usage required to charge a vehicle over a long dwell time. For

use cases with higher energy needs and/or less available dwell time for charging, higherpower chargers may be required to meet the energy needs of EVs.

Regardless of the quantity or power of charging equipment, it is important to keep in mind the additional space necessary for charging dispensers, transformers, and other considerations which may change a site's traffic pattern or "flow."

It is recommended that any chargers installed are networked, which means they include the capability to communicate over cellular networks. Most businesses choose to install networked chargers, due to access control, ensuring that only the fleet's service vehicles can charge at these chargers. Alternatively, fleets can install "behind the fence" non-networked charging in a secure location only accessible to fleet vehicles, assuring the same charging restrictions and availability. However, networked chargers can provide a bevy of technical information, including duration of charge and charge rate, useful for operational planning and decision- making.

Inductive (wireless) charging equipment, which uses an electromagnetic field to transfer electricity to an EV without a cord, is now commercially available as an aftermarket add-on, and has the potential to support rapid medium- and heavy-duty vehicle (MHDV) charging at depots and in warehouse environments where trucks park for extended periods of time, such as loading bays.

Spreading a charging schedule across as many hours as possible will often lead to the lowest capital and operational cost; thus, it is important to weigh various charging solutions against business needs. The next section describes in greater detail some solutions for how this can be addressed.

Charging Equipment

EV charging equipment is classified by battery charging rates. Time to charge will vary depending on battery state of charge, total energy storage, the type of battery, and the type of charging equipment. Charging time can range from less than 20 minutes to 20 hours or more, depending on these factors.

There are three types of charging: Level 1, Level 2, and Level 3 (direct current or DC fast). Level 1 charging is the slowest method and uses a standard alternating current (AC) wall outlet. It adds 2 to 5 miles of range per hour of charging. Because of its slow rate, Level 1 charging is typically only used at home for personal vehicles or workplaces. Level 2 is another AC method that is significantly faster than Level 1. Level 2 is the most common method of charging as it allows most light- and medium-duty vehicles to charge overnight while also being significantly cheaper and easier to install than Level 3 chargers. Level 2 chargers are most commonly found serving commercial vehicles and in public places like parking garages, shopping centers, and tourist attractions. Level 3 DC fast charging is the fastest method of charging, but also the most expensive for both the charger and infrastructure required. These chargers are typically only recommended for heavy-duty trucks and vehicles that dwell for a few hours or less.

Across the United States, there are four major plug types: J1772 ("J-plug"), Tesla (also known as North American Charging Standard or NACS, or SAE J3400), CHAdeMO, and CCS.

- » The J1772 standard is used for Level 1 and 2 AC charging.
- » Tesla is used for Level 2 and 3.
- » CHAdeMO and CCS are used primarily for Level 3 DC fast charging.

While other proprietary plugs exist for MHDVs, these four represent the majority of those in use. The U.S. Department of Transportation National Electric Vehicle Infrastructure (NEVI) Program has standardized federally funded plugs across Level 2 and Level 3 charging, helping build out a national network of publicly-available charging equipment with predictable plug configurations.

In 2022, Tesla opened its previously proprietary charging standard to other EV manufacturers. In the coming years, its NACS will become the most prevalent charger connection. This connector is also referenced as SAE J3400. All connector types are shown below in Figure 1, but fleets should anticipate a growing share of vehicle options to utilize the NACS standard.

Industry leaders have introduced the concept of the Megawatt Charging Solution, designed to provide higher levels of power needed by MHDVs over a shorter period of charging time. Megawatt chargers require significant infrastructure investment (1–3 million volt-amperes or MVA) and may allow for faster adoption of EVs for long-haul trucking. However, most local and regional delivery businesses can be supported by Level 2 or DC fast chargers.

Туре	Level 1 Charging	Level 2 Charging	Level 3 DC Fast Charging	Megawatt
Connector	@			
	J1772	J1772 Tesla/ NACS/ SAE J3400	CHAdeMo CCS Tesla/ NACS/ SAE J3400	MCS
Voltage	120 V AC	208–240 V AC	400 V-1000 V DC	1–3 kV A
Power Output	1 kW	7 kW–19 kW	50–350 kW	900 kW+

FIGURE 1 TYPES OF CHARGERS

Managed Charging

Energy management can greatly decrease operational costs associated with fleet electrification. Managed charging, sometimes called "smart charging," entails the purchase and use of EVSE that can actively track and modulate charging, and a subscription for energy management software provided by the EVSE manufacturer or network provider to keep consumption levels within a predetermined range. While there are additional up-front and monthly costs associated with these technologies, their long-term benefits should also be considered from a total cost of ownership perspective.

Depending on the design of local electricity rates, electricity pricing can be based upon the time of day during which electricity is used, where marginal pricing is greater during times of high demand and lower when strain to the grid is at its lowest. Fleets may also be exposed to demand charges, which are increased electricity chargers incurred from large, simultaneous power draws—such as when multiple heavy-duty trucks plug into fast charging at the same location at the same time. However, charging when electricity costs are lowest is not always feasible or operationally convenient for fleets. Managed charging software automates charging to coincide with dwell times while enabling fleets to benefit from lower electric rates and/or mitigating demand charges.

Pine State Trading could utilize managed charging at both of their domicile locations due to their vehicles having extended downtime (11 hours). This could allow them to charge the vehicles using less equipment rather than procuring one charging port per vehicle.

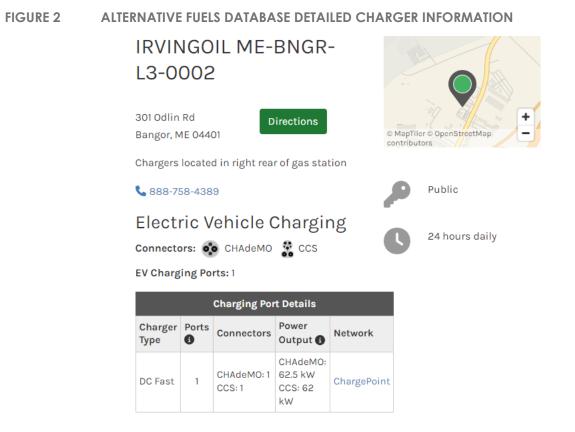

On-Route versus Depot Charging

Most commercial EV deployments currently in operation rely solely on depot charging, or a "return-to-base" schedule where a fleet keeps vehicles parked at one location owned/ leased by the organization operating those vehicles. While policy efforts and Federal funding are advancing the development of strategically sited on-route fast charging and public charging hubs, it is recommended that current EV deployments plan for on-site depot charging, where feasible.

The Alternative Fuels Database, provided by the U.S. DOE, includes a <u>tool</u> to find publicly available charging stations, as does the similar <u>PlugShare</u> tool. Users can also map a route, similar to Google Maps, and see all charging stations along the route. These tools compile data from many networks of charging stations, such as <u>ChargePoint</u>, <u>Electrify America</u>, <u>EVgo</u>, and <u>Tesla</u>. By clicking on a charging station, one can view the number of available charging ports, as well as the type of charging connector.

It is important to note that not all charging stations listed on these sites will be appropriate for charging MHDVs. Most Class 2b and Class 3 vehicles will be able to use charging stations designed for light-duty vehicles, but Class 4–8 vehicles are often too large for typical light-duty vehicle parking spaces, and may require higher power levels to recharge quickly. It is anticipated that most public charging stations for medium- and heavy-duty trucks will require power levels of 150–350kW or more per port, paired with pull-through charging stalls and ample clearance. These may not be available at stations that appear in the DOE or PlugShare tools.

Few DC fast chargers are currently available on-route, and those that do exist may not be able to accommodate a Class 8 truck. The network of available chargers will continue to grow, however; active chargers and hours of operation are updated in these tools on a monthly basis. An example charger that would be convenient for Pine State is shown in Figure 2.

Public chargers such as ChargePoint or EVgo typically require that drivers use a mobile application to interact with the charger and pay for their charge, either through the app itself, or with a credit card at the charger. In 2023, the NEVI program introduced standards for future EVSE installation including provisions that stations must implement non-proprietary charging ports, accept open-access payments such as pay by phone or contactless credit/ debit card, be located along designated FHWA <u>Alternative Fuel Corridors</u>, and be publicly available.

Fueling/Charging Cost Analysis

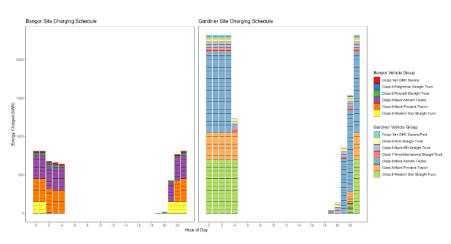

A charging analysis was performed for electrification scenarios for Pine State Trading using CALSTART's Charging Infrastructure Optimization (CHARIOT) Tool. The CHARIOT tool aims to optimize the fleet's charging schedule, to find a schedule that works well with fleet operations while achieving lowest possible energy cost. It also provides a projected energy flow of a fleet's energy consumption and, when applicable, potential for on-site energy generation (e.g., solar power with battery storage) to get a sense of a site's energy independence and grid reliance. Pine State Trading's electricity is provided by Central Maine Power (CMP) at their Gardiner and Augusta sites and by Versant at their Bangor site.

The CHARIOT tool was used twice for Pine State Trading's Gardiner and Bangor sites: once using CMP and Versant's high peak time-of-use (TOU) rate (\$3.55/kWh) and once using a flat TOU rate (\$0.12/kWh).

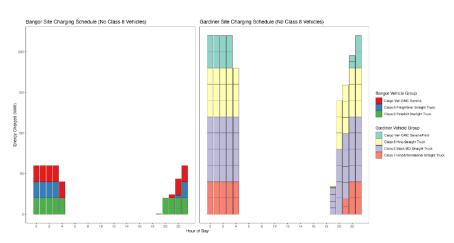

Daily Charging Load Profiles

Figure 3 and Figure 4 show what daily charging profiles (energy demand by hour) might look like for this fleet, for all vehicles and excluding Class 8 vehicles, respectively. Class 8 vehicles are excluded in the second example due to their significant impact on load; Pine State could consider starting electrification with their Class 2b and Class 6 vehicles only. The peak loads calculated with all vehicles are 810 kW for the Bangor site and 2,320 kW for the Gardiner site. The peak loads calculated excluding Class 8 vehicles are 60 kW for the Bangor site and 220 kW for the Gardiner site.

The following figures show total annual energy costs for the base vs. replacement electric vehicle, at each location and under the two electricity pricing scenarios.

The Bangor site—flat TOU rate scenario models a flat time of use rate of \$0.118/kWh and compares with a \$3.70/gallon cost of diesel. Figure 5 compares the annual energy usage for diesel and electric vehicles, while Figure 6 models the cost per mile for each vehicle type. Based on the anticipated energy needs of 18 electric vehicles at the Bangor site compared to 18 gasoline/diesel vehicles, Pine State Trading is estimated to achieve significant reductions to their annual energy costs and cost per mile of operation.

FIGURE 5 BANGOR—FLAT TOU RATE SCENARIO ANNUAL ENERGY COST FOR DIESEL VERSUS EV

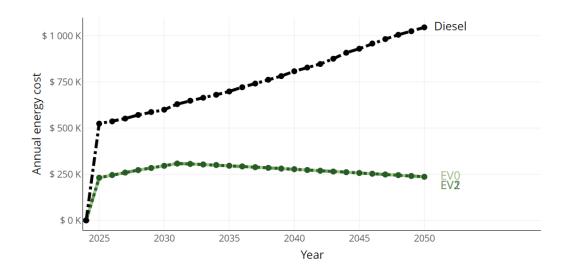

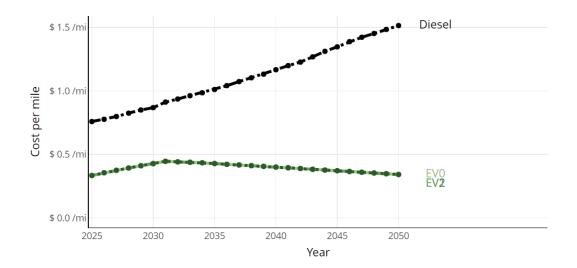

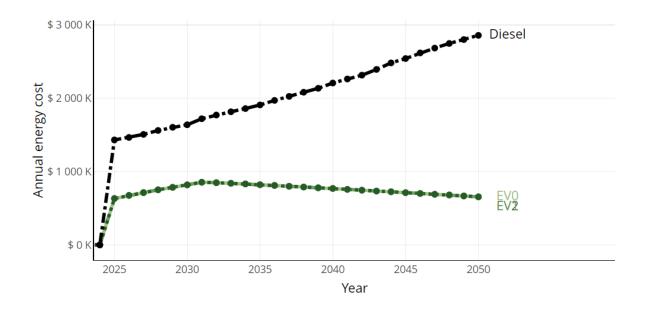

FIGURE 6 BANGOR—FLAT TOU RATE SCENARIO COST PER MILE FOR DIESEL VERSUS EV

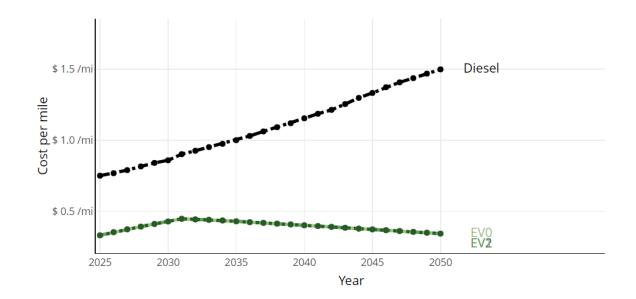

The Gardiner site—flat TOU rate scenario models a flat time of use rate of \$0.118/kWh and compares with a \$3.70/gallon cost of diesel. Figure 7 compares the annual energy usage for diesel and electric vehicles, while Figure 8 models the cost per mile for each vehicle type. Based on the anticipated energy needs of 53 electric vehicles at the Bangor site compared to 53 gasoline and diesel vehicles, Pine State Trading is estimated to achieve significant reductions to their annual energy costs and cost per mile of operation.

EVSE FINANCING

Federal Incentives

Commercial Clean Vehicle Tax Credit

The Federal Government's adoption of the Infrastructure Reduction Act (IRA) enacted new Federal tax credits (IRC Section 45W) for commercial clean (electric or hydrogen fuel cell) vehicles in 2022. Eligible entities include businesses and tax-exempt organizations that purchase commercial clean vehicles between January 1, 2023, and before January 1, 2033. Heavy-duty vehicles with a gross vehicle weight rating of 14,000 lbs. or greater are eligible for a tax credit up to \$40,000, or 30 percent of the incremental cost of the vehicle as compared to a gasoline or diesel vehicle, whichever is lower. Applicable electric vehicles must have a battery with at least 15 kWh of capacity and be made by a qualified manufacturer (see the IRS's list for examples). For tax exempt entities, such as schools, governments, or non-profit organizations, the tax credit is available through a mechanism commonly known as direct, or elective, pay.

Alternative Fuel Infrastructure Tax Credit

Beginning on January 1, 2023, installation of EV charging equipment is eligible for a tax credit of 30 percent of the installation costs (or 6 percent in the case of property subject to depreciation), not to exceed \$100,000. Permitting and inspection fees are not included in covered expenses. As above, tax-exempt entities are eligible to claim these credits through direct or elective pay.

These tax credits are only available to business locations and tax-exempt entities with the following census tract requirements:

- » A population census tract where the poverty rate is at least 20 percent.
- » Metropolitan and non-metropolitan area census tract where the median family income is less than 80 percent of the State median family income level.

Fleets should work with their charging infrastructure installers to determine eligibility by identifying their census tract using <u>this tool</u> and determining if it is included in the <u>IRS's list</u>. If eligible, <u>tax form 8911</u> should be completed.

State Incentives

Efficiency Maine Medium- and Heavy-Duty Vehicle Incentive Pilot

In October 2024, the quasi-state agency Efficiency Maine Trust launched a pilot program to demonstrate potential use cases and performance of zero-emission MHDVs in Maine. Awards will be issued in three rounds, with applications open through the end of February 2025, with the possibility of further rounds of funding in the future. In order to be eligible, applicants must be based in Maine and already own a Class 3 to 7 vehicle in their fleet. The maximum award for different vehicle classes is shown in Table 6.

TABLE 6 EFFICIENCY MAINE INCENTIVE LEVELS

Vehicle Class	Maximum Award
Class 3	40% of purchase price up to \$40,000
Class 4	40% of purchase price up to \$60,000
Class 5	50% of purchase price up to \$80,000
Class 6	50% of purchase price up to \$100,000
Class 7	50% of purchase price up to \$120,000

Along with awards for vehicle purchases, the program also offers incentives for Level 2 charging and professional services such as consulting. For further information, and to apply, fleets should visit <u>the program website</u>.

RESULTS

Total Cost of Ownership

Calculating the total cost of ownership for a vehicle offers fleet owners information to evaluate direct and indirect costs of EV purchases, as well as potential savings over the life cycle of purchased vehicles. The transition to EVs involves a shift in perspective regarding TCO components. Traditional internal combustion engine (ICE) vehicle costs are usually presented as capital cost for vehicles and dollar per gallon (\$/gal) costs for fuel, as well as lifetime maintenance expenses. An analysis of TCO for EVs must consider power output, \$ per kilowatt, grants and incentive programs, and planning and installing EVSE. While EVs are typically more expensive upfront, they are often less expensive to operate and maintain than comparable ICE vehicles; in many cases, these operational savings can offset higher upfront costs across the lifespan of the vehicle, resulting in a positive TCO.

TCO is calculated by combining the vehicle capital and operating costs over a set period of operations. For this analysis, the vehicle price points came from industry averages. Calculations assume a purchase in 2025 and a 12-year vehicle life, which is average across Maine trucks in this class. The results represent one vehicle in each duty cycle. Calculations accounted for the Efficiency Maine Trust vehicle incentives and the Federal Commercial Clean Vehicle tax credit. The results are estimates and actual cost differences may vary.

Each TCO scenario is modeled with a capital procurement cost for the diesel versus electric model and does not include any vehicle resale or residual values. The Federal tax credit is detailed in the <u>Federal Incentives</u> section and, along with Maine state incentives, is taken into consideration when modeling cumulative costs over time. For simplicity, the TCO calculation includes procurement of EVSE and infrastructure upgrades based on the cost of a single port. Infrastructure upgrade costs are calculated per location, not per vehicle. Those costs are modeled in the <u>Fueling/Charging Cost Analysis</u> section. The included costs are vehicle procurement, sales tax, Federal excise tax, maintenance, fuel, and insurance costs. Level 2 charging was assumed for Pine State Trading's GMC Savanna vans, Ford Transit vans, and Class 6 straight trucks. Level 3 DC fast charging was assumed for their Class 7 and Class 8 trucks.

Ford Transit/GMC Savanna Van

Pine State Trading's three Ford Transit/GMC Savanna vans have an average annual mileage of up to 16,000 miles and operate 255 days per year, meaning their daily driving distance is up to about 63 miles. Figure 9 shows cumulative costs over time and Figure 10 shows itemized total costs.

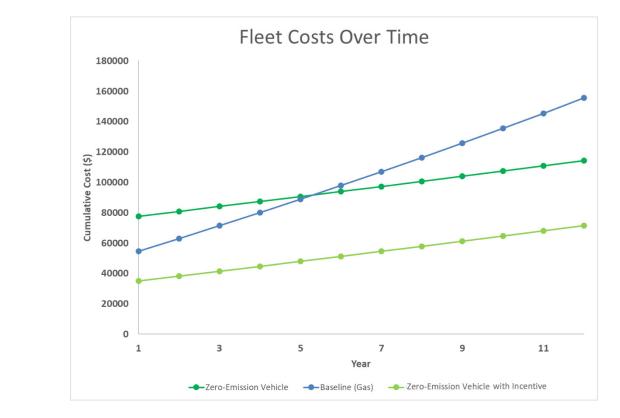

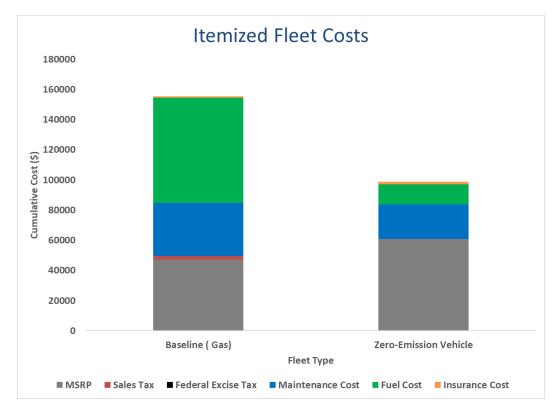

FIGURE 9 FORD TRANSIT/GMC SAVANNA VAN—FLEET COSTS OVER TIME

This TCO analysis compares a gasoline-powered cargo van priced at \$47,000 with an electric cargo van priced at \$61,000. It assumes a \$3.50/gallon price of gasoline and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$12,200 for the costs of one Level 2 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$24,400 off the purchase vehicle price. The Commercial Clean Vehicle Tax Credit removes \$18,300 more (30 percent of the vehicle manufacturers' suggested retail price, or MSRP), reducing the procurement cost further to \$34,729.

The results indicate that the cargo van's payback period is five years without the incentive and that the electric vehicle produces savings at the point of purchase with the incentive. The electric cargo van produce estimated annual fuel costs savings of 136 percent (\$6,321) and estimated annual maintenance costs savings of 42 percent (\$1,750), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts) Itemized costs are shown in Table 7.

 TABLE 7
 FORD TRANSIT VAN ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
MSRP	\$47,000	\$61,000
Sales Tax	\$2,585	\$3,355
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$26,400	\$17,160
Fuel Cost	\$52,150	\$9,936
Insurance Cost	\$1,227	1,592
Infrastructure Costs	\$0	\$12,200

Class 6 Truck

Pine State Trading's nine Class 6 trucks have an average annual mileage of up to 20,000 miles and operate 255 days per year, meaning their daily driving distance is up to about 79 miles. Figure 11 shows cumulative costs over time and Figure 12 shows itemized total costs.

FIGURE 11 CLASS 6—FLEET COSTS OVER TIME

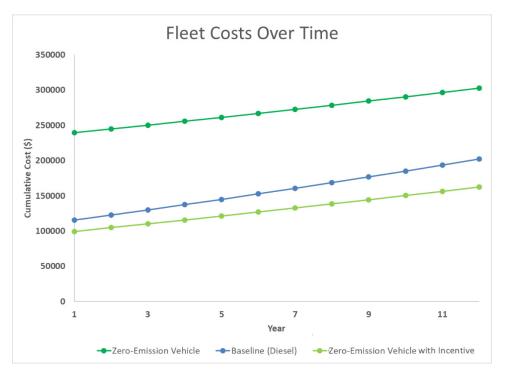

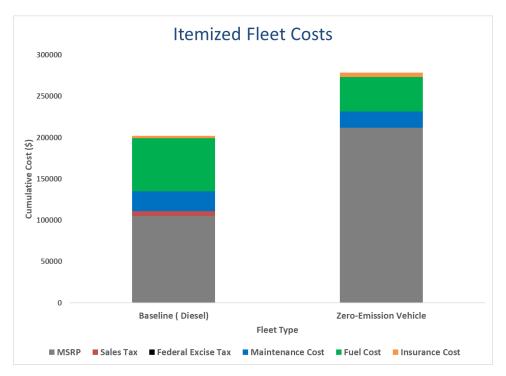

FIGURE 12 CLASS 6—ITEMIZED FLEET COSTS

This TCO analysis compares a diesel-powered truck priced at \$105,000 with an electric truck priced at \$212,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of

charging. The infrastructure cost is priced at \$12,200 for the costs of one Level 2 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$100,000 off the purchase vehicle price, reducing the capital procurement cost to \$141,512. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$101,512.

The results indicate that the Class 6 truck's payback period exceeds its expected life without the incentive but produces savings immediately with the incentives included. The electric Class 6 truck also produces an estimated 43% reduction in annual fuel costs (\$2,742) and an estimated 22 percent reduction in annual maintenance costs (\$760), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 8.

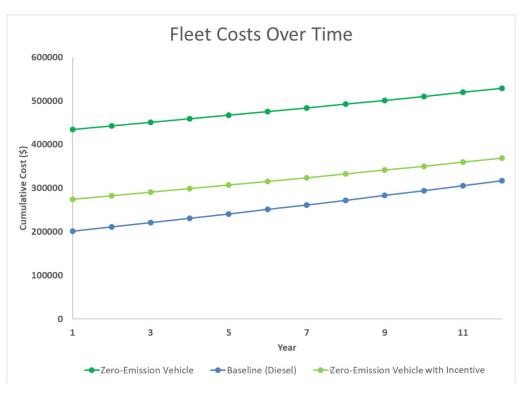

TABLE 8 CLASS 6 ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
MSRP	\$105,000	\$212,000
Sales Tax	\$5,775	\$11,660
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$41,800	\$33,440
Fuel Cost	\$111,368	\$72,105
Insurance Cost	\$2,741	\$5,533
Infrastructure Costs	\$O	\$12,200

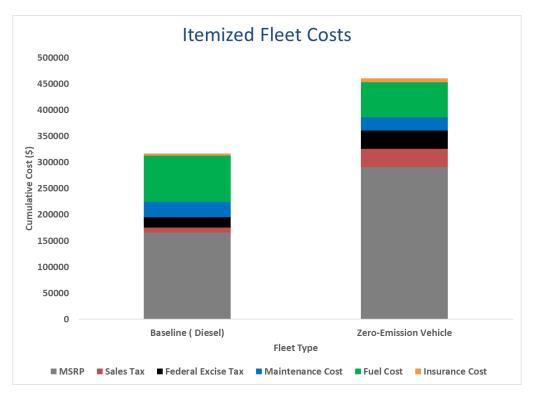

Class 7 Truck

Pine State Trading's two Class 7 trucks have an average annual mileage of 15,000 miles and operate 255 days per year, meaning their daily driving distance about 59 miles. Figure 13 shows cumulative costs over time and Figure 14 shows itemized total costs.

This TCO analysis compares a diesel-powered truck priced at \$166,000 with an electric truck priced at \$291,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,450 for the costs of one Level 3 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$120,000 off the purchase vehicle price, reducing the capital procurement cost to \$141,512. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$101,512.

The results indicate that the Class 7 truck's payback period exceeds its expected life but with and without the incentives included due to higher upfront capital costs. The electric Class 7 truck still produces an estimated 27 percent reduction in annual fuel costs (\$1,445) and an estimated 18 percent reduction in annual maintenance costs (\$450), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 9Table 8.

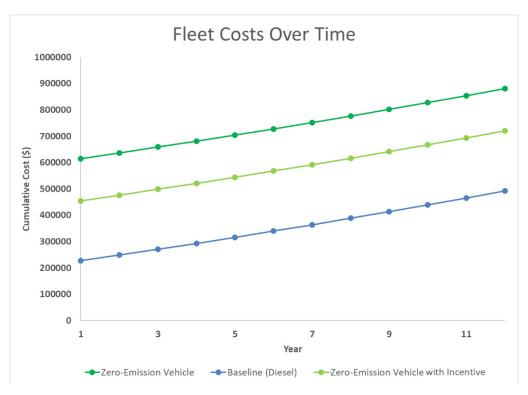

TABLE 9 CLASS 7 ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
MSRP	\$105,000	\$212,000
Sales Tax	\$5,775	\$11,660
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$41,800	\$33,440
Fuel Cost	\$111,368	\$72,105
Insurance Cost	\$2,741	\$5,533
Infrastructure Costs	\$0	\$87,450

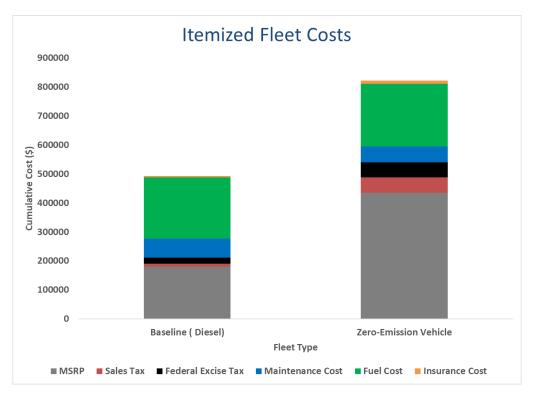

Class 8 Truck

Pine State Trading's 57 Class 8 trucks have an average annual mileage of up to 33,000 miles and operate 255 days per year, meaning their daily driving distance is up to about 129 miles. Figure 15 shows cumulative costs over time and Figure 16 shows itemized total costs.

This TCO analysis compares a diesel-powered truck priced at \$180,000 with an electric truck priced at \$435,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$120,000 off the purchase vehicle price, reducing the capital procurement cost to \$494,528. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$454,528.

The results indicate that the Class 8 truck's payback period exceeds its expected life but with and without the incentives included due to higher upfront capital costs. The electric truck produces estimated annual maintenance costs savings of 18 percent (\$990), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 10.

Cost Components	Baseline	ZEV
MSRP	\$105,000	\$212,000
Sales Tax	\$5,775	\$11,660
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$41,800	\$33,440
Fuel Cost	\$111,368	\$72,105
Insurance Cost	\$2,741	\$5,533
Infrastructure Costs	\$0	\$87,450

Fleet Emissions

Maine's transportation sector is the largest source of greenhouse emissions in the State, and medium- and heavy-duty trucks account for 27 percent of these emissions.¹ Providing power to vehicles via electricity is significantly less polluting than diesel fuel, especially in areas served by low-carbon sources of electricity generation. Renewable resources powered

¹ Rocky Mountain Institute. "<u>RMI Analysis: With Smart Policy, Truck Electrification Is Within Reach</u>." Accessed October 2024.

Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles Case Study: Fleet 1

64 percent of Maine's total electricity net generation, and wind provided the largest share at 23 percent of the State's total net generation, in 2022.²

An analysis of Pine State Trading' direct exhaust emissions was performed using the U.S. Environmental Protection Agency's Diesel Emission Quantifier tool. The analysis combines the average annual mileage traveled by all diesel vehicles in the fleet. Converting Fleet 1's vehicles to ZEVs would eliminate all of these direct emissions.

TABLE 11 INTERNAL COMBUSTION ENGINE FLEET EMISSIONS

Pollutant	Annual Emissions (Short Tons/Year)	10-Year Emissions (Short Tons)
Carbon Monoxide (CO)	3.726	37.26
Nitrogen Oxides (NO _x)	5.277	52.77
Particulate Matter (PM)	0.009	0.09
Carbon Dioxide (CO2)	3,376	33,764

IMPLEMENTATION CONSIDERATIONS

Energy Storage and Resiliency

Power outages are always a possibility at fleet depots, regardless of grid advancements and fidelity. Fleets should consider contingencies for maintaining operations of electric trucks in the event of a long-term power outage. Today's electric vehicles do not necessarily require electricity from the grid to be available to properly fuel. There are means of fueling battery-electric vehicles using energy storage solutions, most commonly batteries, which are safer than storing flammable fossil fuels on site. Critical vehicle operations may consider other forms of backup power to ensure charging access, including generators.

Many consumers have asked whether EVs can be used in an emergency to provide backup power to homes, offices, and other facilities. For a vehicle to provide backup power, there are several additional considerations: whether the vehicle is designed for 'bidirectional charging', meaning that the vehicle can output power, and whether the facility has appropriate two-way charging equipment. The Ford F-150 Lightning is equipped to support

² U.S. Energy Information Administration. <u>State Profile and Energy Estimates</u>. Accessed October 2024.

bidirectional charging, and Ford supports claims that the truck can provide up to 100 kWh of power on a single charge, which is enough to power an average house for three days (30 kWh per day).

Preheat/Precool

One consideration often overlooked in commercial EV operation is the energy use associated with climate control, either for the operator or for the goods themselves. Idle time spent bringing a cab to a comfortable riding temperature uses energy otherwise intended for moving the vehicle along its intended route. The energy used to heat or cool the vehicle cabin may consume a significant amount of the vehicle's battery capacity. Preconditioning while vehicles are connected to chargers at the depot is a simple approach to providing comfortable conditions and extending driving range during winter and summer. These types of considerations are important to factor in, and experiment with, during a fleet's initial deployment.

"Vampire" Energy

Vehicles of all kinds are meant to be driven; they benefit from regular usage by foregoing the potential negative impacts of remaining idle for extended periods. One such impact to commercial EVs is what is known as "vampire" energy, where a vehicle's battery will slowly deplete while it remains unplugged and idle. This is normal behavior and not an indication that anything is malfunctioning. Rather, this is an expected effect resulting from a combination of onboard electronics that remain on or in stand-by, as well as the natural chemical reactions occurring in a vehicle's battery.

Best practices for long-term battery health include keeping a vehicle's battery charged to 80 percent when possible and taking measures to ensure its state of charge does not regularly fall below 20 percent while idle. Managed and networked charging infrastructure can help fleets keep battery state of charge within this optimal range. For smaller EV deployments and fleets involving just a few vehicles, this also may be achievable through effective training and communication with staff on-site.

SUMMARY

Fleet 2, Lynch Logistics is a full-service logistics and transportation provider doing business throughout Maine, the U.S., and Canada. This report assesses their vehicles which domicile on Rice Street (RMC/SOS), as well as the shredding facility on Odlin Road (Lynch Logistics), and the maintenance facility on Lexington Drive (MEMoving/MEDelivery), all located in Bangor.

The medium-duty trucks at the Rice Street facility travel approximately 135 miles a day and are primarily used for commercial moving. Their travel patterns and overnight dwell times are well-suited to electric or hydrogen vehicles, and transitioning to these zero-emission alternatives would result in immediate fuel and maintenance cost savings. Despite that, a zero-emission replacement is not projected to produce lifetime savings due to high upfront capital costs for electric and hydrogen trucks.

The Odlin facility houses both gasoline Ford Transit vans which pick up classified materials, and Class 6/7 trucks which serve as on-site mobile shredding units. Even without incentives, electrification of the vans results in cost savings within the first four years of ownership; with incentives, savings are immediate. With incentives, the electrification of the Class 6 trucks is also immediately lower cost than the internal combustion alternative. Although the zero-emissions transition would result in immediate maintenance and fuel cost savings for the Class 7 trucks, there are not projected to be lifetime savings due to the high upfront capital costs.

The Class 8 trucks operating out of the Lexington Drive facility travel between 250–280 miles per day and are primarily used for moving freight. These vehicles can be away from the domicile location for up to two weeks at a time, and would need to rely on on-route charging for electric alternatives. These trucks could be replaced with hydrogen fuel cell vehicles, where longer ranges are available, though more significant fueling station infrastructure challenges exist. Though fuel and maintenance cost savings are immediate, there are no lifetime savings due to the high upfront costs of Class 8 vehicles.

INTRODUCTION

The Maine Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles ("roadmap") charts a path for Maine to decarbonize the trucks and buses moving people and goods within and through the State. As part of the roadmap, the project team has conducted a series of case studies with Maine businesses to identify real world opportunities and challenges for fleet electrification. The case studies are intended to 1) serve the participating fleets by providing customized fleet electrification assessments; and 2) augment the roadmap by evaluating electrification use cases, total cost of ownership, and barriers in the context of actual Maine business operations.

Fleet Information

Lynch Logistics operates from three warehouses providing various logistical services. At the Lexington Drive warehouse, 30 vehicles provide freight pickup and delivery services. At Rice Street, six vehicles provide commercial moving services. From the Odlin Road warehouse, fifteen vehicles provide pickup and shredding services for confidential materials. Vehicles at the latter two warehouses domicile overnight at their respective lots, while Lexington Drive vehicles have more irregular schedules and may be on the road for days at a time. Table 1 shows an inventory of the fleet.

Vehicle Group	Vehicle Quantity	Vehicle Class	Fuel Type	Manufacturing Year (average)	Average Annual Miles	Owned or Leased Vehicles
Ford Transit Van	2	Class 3–10,001– 14,000 lbs.	Gas	2019	25,000	Owned
Chevy 4500 Box Truck	1	Class 4–14,001– 16,000	Diesel	2019	35,000	Owned
Freightliner M2106	13	Class 6–19,501– 26,000 lbs.	Diesel	2019	35,000	Owned
Freightliner M2106	5	Class 7–26,001– 33,000 lbs.	Diesel	2019	35,000	Owned
Freightliner 122SD	2	Class 8–Over 33,000 lbs.	Diesel	2023	65,000	Owned
Freightliner Cascadia	27	Class 8–Over 33,000 lbs.	Diesel	2022	75,000	Owned

TABLE 1 LYNCH LOGISTICS VEHICLE INVENTORY

Vehicle Recommendations

To adequately define the needs of a fleet, the vehicles used are categorized into duty cycles. Duty cycles are classifications that describe both the vehicle, by type and class, and *how it is operated*, including typical miles traveled, type of use (local versus highway), and fuel consumption.

Vehicle recommendations are not exhaustive of all options that may be on the market; selections are included based on those most likely to meet Fleet 2's duty cycles.

Ford Transit Van

Lynch Logistics operate two Ford Transit vans that drive an average of 96 miles per day and dwell for 13 hours overnight at the RMC/SOS—Bangor facility. These vehicles are used to pick up and transfer confidential materials. All recommendations shown in Table 2 can meet Lynch's current duty cycle.

Chevy 4500 Box Truck

Lynch Logistics operate one Chevy 4500 box trucks that drives an average of 135 miles per day and dwells for 12 hours overnight at the MEMoving/MEDelivery facility. This vehicle is used for commercial moving. Due to their higher available ranges, the Phoenix Motorcars Box Truck and the Bollinger Motors B4 are best suited to meet Lynch's duty cycle on a single charge. Other models may utilize public DC Fast charging to quickly recharge and finish a route. Replacement options are shown in Table 3.

Freightliner M2106—Class 6

Lynch Logistics operate 13 Class 6 Freightliner M2106 trucks that drive an average of 135 miles per day and dwell for 12 hours overnight at the MEMoving/MEDelivery facility. These vehicles are used for last-mile delivery commercial moving. All recommendations shown in Table 4 can meet Lynch's current duty cycle, though DC Fast charging is recommended to allow the vehicles to fully charge within their scheduled dwell time.

TABLE 4 FREIGHTLINER M2106—CLASS 6 REPLACEMENTS

Freightliner M2106—Class 7

Lynch Logistics operates five Class 7 Freightliner M2106 trucks that drive an average of 135 miles per day and dwell for 12.5 hours overnight at the RMC-SOS Bangor facility. These vehicles are used as on-site mobile shredding units. Most Class 6 recommendations are also available as a Class 7 build, with the addition of the Kenworth K370E. All recommended models can fulfill Lynch's duty cycle using DC fast charging, which is typically used by Class 7 trucks. Table 5 shows recommended replacement options.

TABLE 5 FREIGHTLINER M2106—CLASS 7 REPLACEMENTS

Class 8 Trucks

Lynch Logistics operate 30 Class 8 trucks (two Freightliner 122SDs, 27 Freightliner Cascadias, and one Western Star 49X). The Freightliner 122SDs and Western Star 49X drive an average of 250 miles per day, while the Freightliner Cascadias drive an average of 289 miles per day. All 30-vehicle domicile at the Lynch Logistics facility and do not have a set schedule, meaning their daily dwell time varies. All recommended models can either meet Lynch's duty cycle on a single charge or with a quick DC fast charge mid-route, as long as they dwell for at least 1-2.5 hours before restarting travel. Table 6 shows recommended replacement options.

TABLE 6 CLASS 8 ELECTRIC VEHICLE REPLACEMENTS

Alternatively, Fleet 2 can explore the hydrogen fuel cell options listed in Table 7. Hydrogen fuel cells allow for faster refueling and longer ranges in some cases. Fuel cell vehicles require a source of hydrogen for refueling, which could be either privately or publicly owned. The U.S. Department of Energy (DOE) has awarded projects to expand a nationwide hydrogen refueling corridor, however the capital to install and run a hydrogen refueling station is significant, in the million-dollar range. Many fleets could benefit from public hydrogen stations, paying for the fuel but not the infrastructure.

CHARGING AND INFRASTRUCTURE

Fleet Electrification Overview

Fleet electrification involves coordination between the fleet and their electric utility, contractors, developers, vehicle original equipment manufacturers, and electric vehicle service providers to determine the power, quantity, and arrangement of electric vehicle supply equipment (EVSE), or vehicle charging, for a particular site. Once vehicle quantity and duty cycles are defined, the quantity and power of EVSE needed can be determined. In most fleet charging configurations, it is typical to install one dedicated charging plug per electric vehicle (EV). This is to support overnight charging, when electricity rates are low and vehicles are ordinarily not in operation; overnight charging typically lends itself to less costly EVSE due to the lower power usage required to charge a vehicle over a long dwell time. For use cases with higher energy needs and/or less available dwell time for charging, higher-power chargers may be required to meet the energy needs of EVs.

Regardless of the quantity or power of charging equipment, it is important to keep in mind the additional space necessary for charging dispensers, transformers, and other considerations which may change a site's traffic pattern or "flow."

It is recommended that any chargers installed are networked, which means they include the capability to communicate over cellular networks. Most businesses choose to install networked chargers, due to access control, ensuring that only the fleet's service vehicles can charge at these chargers. Alternatively, fleets can install "behind the fence" non-networked charging in a secure location only accessible to fleet vehicles, assuring the same charging restrictions and availability. However, networked chargers can provide a bevy of technical information, including duration of charge and charge rate, useful for operational planning and decision- making.

Inductive (wireless) charging equipment, which uses an electromagnetic field to transfer electricity to an EV without a cord, is now commercially available as an aftermarket add-on, and has the potential to support rapid medium- and heavy-duty vehicle (MHDV) charging at depots and in warehouse environments where trucks park for extended periods of time, such as loading bays. Spreading a charging schedule across as many hours as possible will often lead to the lowest capital and operational cost; thus, it is important to weigh various charging solutions against business needs. The next section describes in greater detail some solutions for how this can be addressed.

Charging Equipment

EV charging equipment is classified by battery charging rates. Time to charge will vary depending on battery state of charge, total energy storage, the type of battery, and the type of charging equipment. Charging time can range from less than 20 minutes to 20 hours or more, depending on these factors.

There are three types of charging: Level 1, Level 2, and Level 3 (direct current or DC fast). Level 1 charging is the slowest method and uses a standard alternating current (AC) wall outlet. It adds 2 to 5 miles of range per hour of charging. Because of its slow rate, Level 1 charging is typically only used at home for personal vehicles or workplaces. Level 2 is another AC method that is significantly faster than Level 1. Level 2 is the most common method of charging as it allows most light- and medium-duty vehicles to charge overnight while also being significantly cheaper and easier to install than Level 3 chargers. Level 2 chargers are most commonly found serving commercial vehicles and in public places like parking garages, shopping centers, and tourist attractions. Level 3 DC fast charging is the fastest method of charging, but also the most expensive for both the charger and infrastructure required. These chargers are typically only recommended for heavy-duty trucks and vehicles that dwell for a few hours or less.

Across the United States, there are four major plug types: J1772 ("J-plug"), Tesla (also known as North American Charging Standard or NACS, or SAE J3400), CHAdeMO, and CCS.

- » The J1772 standard is used for Level 1 and 2 AC charging.
- » Tesla is used for Level 2 and 3.
- » CHAdeMO and CCS are used primarily for Level 3 DC fast charging.

While other proprietary plugs exist for MHDVs, these four represent the majority of those in use. The U.S. Department of Transportation National Electric Vehicle Infrastructure (NEVI) Program has standardized federally funded plugs across Level 2 and Level 3 charging, helping build out a national network of publicly-available charging equipment with predictable plug configurations.

In 2022, Tesla opened its previously proprietary charging standard to other EV manufacturers. In the coming years, its NACS will become the most prevalent charger connection. This connector is also referenced as SAE J3400. All connector types are shown below in Figure 1, but fleets should anticipate a growing share of vehicle options to utilize the NACS standard.

Industry leaders have introduced the concept of the Megawatt Charging Solution, designed to provide higher levels of power needed by MHDVs over a shorter period of charging time. Megawatt chargers require significant infrastructure investment (1–3 million volt-amperes or MVA) and may allow for faster adoption of EVs for long-haul trucking. However, most local and regional delivery businesses can be supported by Level 2 or DC fast chargers.

Туре	Level 1 Charging	Level 2 Charging	Level 3 DC Fast Charging	Megawatt
Connector	J1772	J1772 Tesla/ NACS/ SAE J3400	CHAdemo CCS Tesla/ NACS/ SAE J3400	MCS
Voltage	120 V AC	208–240 V AC	400 V-1000 V DC	1–3 kV A
Power Output	1 kW	7 kW–19 kW	50–350 kW	900 kW+

FIGURE 1 TYPES OF CHARGERS

Managed Charging

Energy management can greatly decrease operational costs associated with fleet electrification. Managed charging, sometimes called "smart charging," entails the purchase and use of EVSE that can actively track and modulate charging, and a subscription for energy management software provided by the EVSE manufacturer or network provider to keep consumption levels within a predetermined range. While there are additional up-front and monthly costs associated with these technologies, their long-term benefits should also be considered from a total cost of ownership perspective. Depending on the design of local electricity rates, electricity pricing can be based upon the time of day during which electricity is used, where marginal pricing is greater during times of high demand and lower when strain to the grid is at its lowest. Fleets may also be exposed to demand charges, which are increased electricity chargers incurred from large, simultaneous power draws—such as when multiple heavy-duty trucks plug into fast charging at the same location at the same time. However, charging when electricity costs are lowest is not always feasible or operationally convenient for fleets. Managed charging software automates charging to coincide with dwell times while enabling fleets to benefit from lower electric rates and/or mitigating demand charges.

Lynch Logistics could utilize managed charging at their RMC/SOS-Bangor and MEMoving/ MEDelivery warehouses, where their vehicles have extended downtime. This could allow them to charge the vehicles using less equipment rather than procuring one charging port per vehicle.

On-Route versus Depot Charging

Most commercial EV deployments currently in operation rely solely on depot charging, or a "return-to-base" schedule where a fleet keeps vehicles parked at one location owned/ leased by the organization operating those vehicles. While policy efforts and Federal funding are advancing the development of strategically sited on-route fast charging and public charging hubs, it is recommended that current EV deployments plan for on-site depot charging, where feasible.

The Alternative Fuels Database, provided by the U.S. DOE, includes a <u>tool</u> to find publicly available charging stations, as does the similar <u>PlugShare</u> tool. Users can also map a route, similar to Google Maps, and see all charging stations along the route. These tools compile data from many networks of charging stations, such as <u>ChargePoint</u>, <u>Electrify America</u>, <u>EVgo</u>, and <u>Tesla</u>. By clicking on a charging station, one can view the number of available charging ports, as well as the type of charging connector.

It is important to note that not all charging stations listed on these sites will be appropriate for charging MHDVs. Most Class 2b and Class 3 vehicles will be able to use charging stations designed for light-duty vehicles, but Class 4–8 vehicles are often too large for typical light-duty vehicle parking spaces, and may require higher power levels to recharge quickly. It is anticipated that most public charging stations for medium- and heavy-duty trucks will require

power levels of 150–350kW or more per port, paired with pull-through charging stalls and ample clearance. These may not be available at stations that appear in the DOE or PlugShare tools.

Few DC fast chargers are currently available on-route, and those that do exist may not be able to accommodate a Class 8 truck. The network of available chargers will continue to grow, however; active chargers and hours of operation are updated in these tools on a monthly basis. An example charger that would be convenient for Fleet 2 is shown in Figure 2.

Public chargers such as ChargePoint or EVgo typically require that drivers use a mobile application to interact with the charger and pay for their charge, either through the app itself, or with a credit card at the charger. In 2023, the NEVI program introduced standards for future EVSE installation including provisions that stations must implement non-proprietary charging ports, accept open-access payments such as pay by phone or contactless credit/ debit card, be located along designated FHWA <u>Alternative Fuel Corridors</u>, and be publicly available.

Fueling/Charging Cost Analysis

A charging analysis was performed for electrification scenarios for Fleet 2 using CALSTART's Charging Infrastructure Optimization (CHARIOT) Tool. The CHARIOT tool aims to optimize Fleet 2's charging schedule, to find a schedule that works well with fleet operations while achieving lowest possible energy cost. It also provides a projected energy flow of a fleet's energy consumption and, when applicable, potential for on-site energy generation (e.g., solar power with battery storage) to get a sense of a site's energy independence and grid reliance. Fleet 2's electricity is provided by Central Maine Power (CMP).

The CHARIOT tool was used twice for each warehouse: once using Versant's high peak timeof-use (TOU) rate (\$3.55/kWh) and once using a flat TOU rate (\$0.12/kWh). Peak loads were calculated for each of the three sites as follows: RMC/SOS (Odlin)—690 kW; ME Moving/ME Delivery (Rice)—300 kW; Lynch Logistics (Lexington)—3,000 kW.

Daily Charging Load Profiles

Figure 3 and Figure 4 show what daily charging profiles (energy demand by hour) might look like for this fleet, for all vehicles and excluding Class 8 vehicles, respectively.

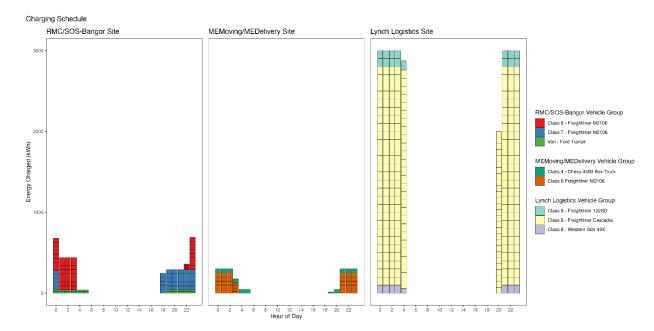

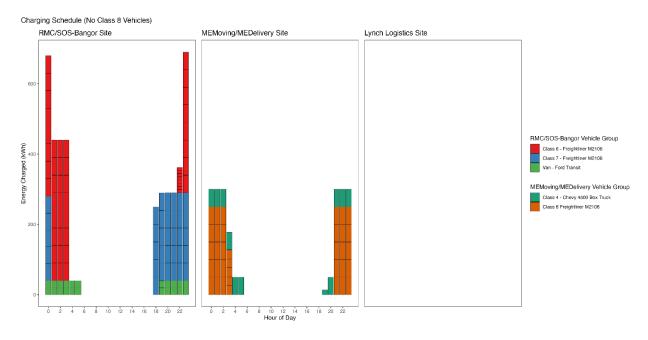

FIGURE 3 DAILY CHARGING LOAD PROFILES—ALL VEHICLES

The following figures show total annual energy costs for the base versus replacement electric vehicle, at each location and under the two electricity pricing scenarios.

The MC/SOS—flat TOU rate scenario models a flat time of use rate of \$0.118/kWh and compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the Odlin Street (RMS/SOS) facility. Figure 5 compares the annual energy usage for diesel and electric vehicles, while Figure 6 models the cost per mile for each vehicle type.

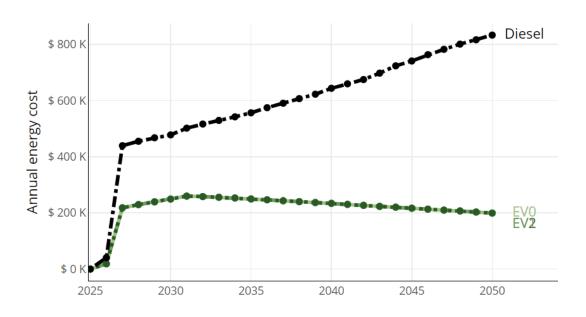

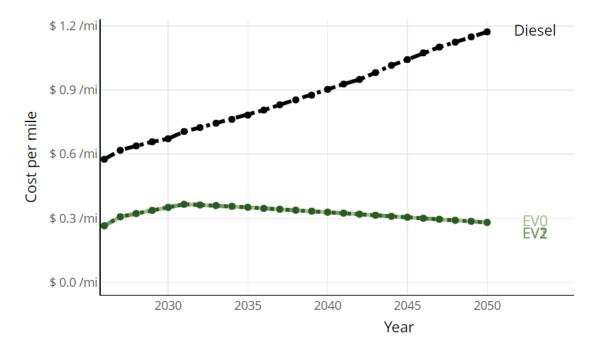

FIGURE 5 RMC/SOS—FLAT TOU RATE SCENARIO ANNUAL ENERGY COST FOR DIESEL VERSUS EV

The RMC/SOS—high peak rate scenario models a time of use rate of \$0.118/kWh (80 percent of charging time) with a \$3.55/kWh peak rate (20 percent of charging time) and compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the Odlin Street (RMS/SOS) facility. Figure 7 compares the annual energy usage for diesel and electric vehicles, while Figure 8 models the cost per mile for each vehicle type.

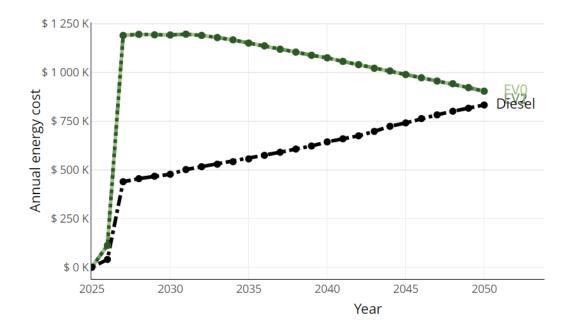

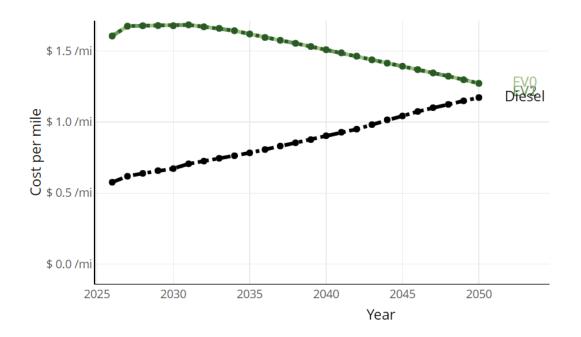

FIGURE 7 RMC/SOS—HIGH PEAK RATE SCENARIO ANNUAL ENERGY COST FOR DIESEL VERSUS EV

The MEMoving/MEDelivery—flat TOU rate scenario models a time of use rate of \$0.118/kWh and compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the Rice St. (MEMoving/MEDelivery) facility. Figure 9 compares the annual energy usage for diesel and electric vehicles, while Figure 10 models the cost per mile for each vehicle type.

MEMOVING/MEDELIVERY—FLAT TOU RATE SCENARIO ANNUAL ENERGY COST FOR DIESEL VERSUS EV

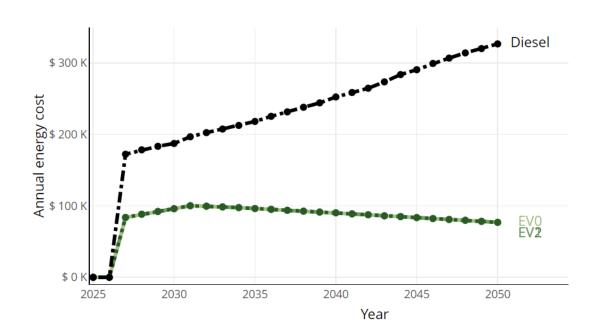

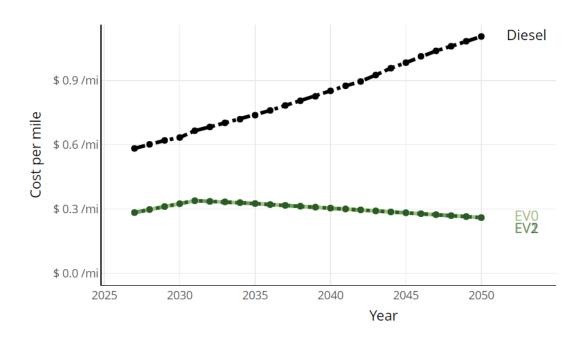

FIGURE 10 MEMOVING/MEDELIVERY—FLAT TOU RATE SCENARIO COST PER MILE FOR DIESEL VERSUS EV

The MEMoving/MEDelivery—high peak rate scenario models a time of use rate of \$0.118/kWh (80 percent of charging time) with a \$3.55/kWh peak rate (20 percent of charging time) and

compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the Rice St. (MEMoving/MEDelivery) facility. Figure 11 compares the annual energy usage for diesel and electric vehicles, while Figure 12 models the cost per mile for each vehicle type.

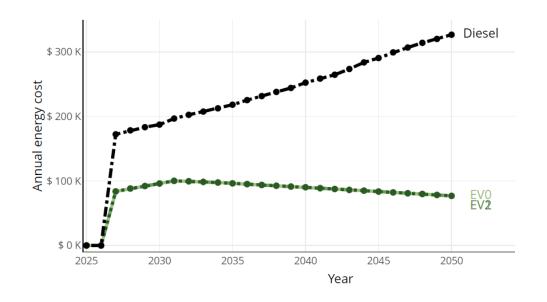

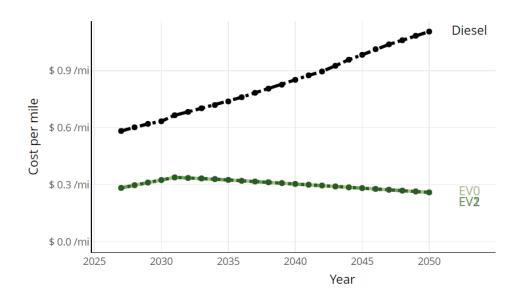

FIGURE 11 MEMOVING/MEDELIVERY—HIGH PEAK RATE SCENARIO ANNUAL ENERGY COST FOR DIESEL VERSUS EV

The Lynch Logistics (Lexington Drive)—flat TOU rate scenario models a time of use rate of \$0.118/kWh and compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the

Rice St. (MEMoving/MEDelivery) facility. Figure 13 compares the annual energy usage for diesel and electric vehicles, while Figure 14 models the cost per mile for each vehicle type.

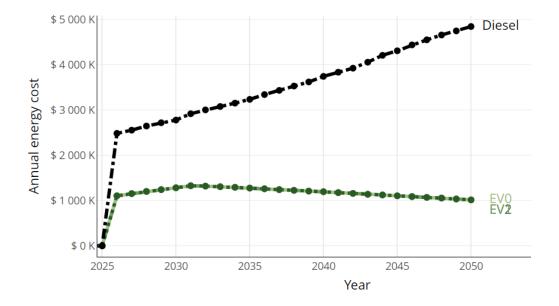

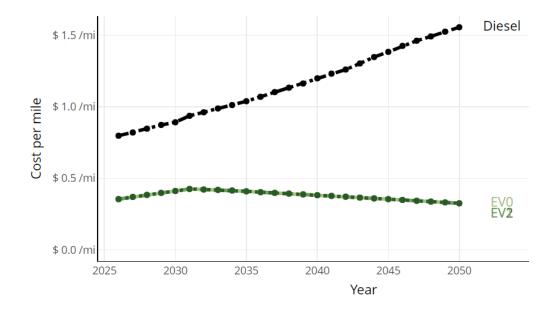

FIGURE 14 LYNCH LOGISTICS (LEXINGTON DRIVE)—FLAT TOU RATE SCENARIO COST PER MILE FOR DIESEL VERSUS EV

The Lynch Logistics (Lexington Drive)—high peak rate scenario models a time of use rate of \$0.118/kWh (80 percent of charging time) with a \$3.55/kWh peak rate (20 percent of

charging time) and compares with a \$3.70/gallon cost of diesel for the vehicles domiciling at the Lexington Drive (Lynch Logistics) facility. Figure 15 compares the annual energy usage for diesel and electric vehicles, while Figure 16 models the cost per mile for each vehicle type.

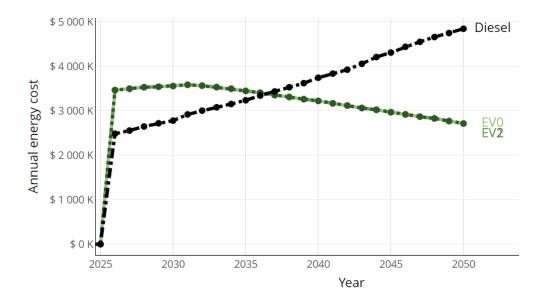

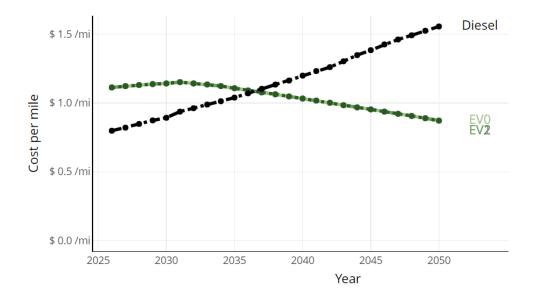

FIGURE 16 LYNCH LOGISTICS (LEXINGTON DRIVE)—HIGH PEAK RATE SCENARIO COST PER MILE FOR DIESEL VERSUS EV

Based on the anticipated energy needs of 51 medium- and heavy-duty vehicles across three warehouses, Lynch Logistics would be estimated to achieve significant reductions in their annual energy costs. The only exception is a high peak rate scenario at the RMC/SOS-Bangor warehouse, where medium and heavy-duty vehicle charging would be more expensive than diesel fueling. Due to the reduced cost of charging compared to diesel fuel, Lynch Logistics could expect a significantly decreased cost per mile of operation, particularly in the flat rate scenario.

EVSE FINANCING

Federal Incentives

Commercial Clean Vehicle Tax Credit

The Federal Government's adoption of the Infrastructure Reduction Act (IRA) enacted new Federal tax credits (IRC Section 45W) for commercial clean (electric or hydrogen fuel cell) vehicles in 2022. Eligible entities include businesses and tax-exempt organizations that purchase commercial clean vehicles between January 1, 2023, and before January 1, 2033. Heavy-duty vehicles with a gross vehicle weight rating of 14,000 lbs. or greater are eligible for a tax credit up to \$40,000, or 30 percent of the incremental cost of the vehicle as compared to a gasoline or diesel vehicle, whichever is lower. Applicable electric vehicles must have a battery with at least 15 kWh of capacity and be made by a qualified manufacturer (see the IRS's list for examples). For tax exempt entities, such as schools, governments, or non-profit organizations, the tax credit is available through a mechanism commonly known as <u>direct, or elective, pay</u>.

Alternative Fuel Infrastructure Tax Credit

Beginning on January 1, 2023, installation of EV charging equipment is eligible for a tax credit of 30 percent of the installation costs (or 6 percent in the case of property subject to depreciation), not to exceed \$100,000. Permitting and inspection fees are not included in covered expenses. As above, tax-exempt entities are eligible to claim these credits through direct or elective pay. These tax credits are only available to business locations and tax-exempt entities with the following census tract requirements:

- » A population census tract where the poverty rate is at least 20 percent.
- » Metropolitan and non-metropolitan area census tract where the median family income is less than 80 percent of the State median family income level.

Fleets should work with their charging infrastructure installers to determine eligibility by identifying their census tract using <u>this tool</u> and determining if it is included in the <u>IRS's list</u>. If eligible, <u>tax form 8911</u> should be completed.

State Incentives

Efficiency Maine Medium- and Heavy-Duty Vehicle Incentive Pilot

In October 2024, the quasi-state agency Efficiency Maine Trust launched a pilot program to demonstrate potential use cases and performance of zero-emission MHDVs in Maine. Awards will be issued in three rounds, with applications open through the end of February 2025, with the possibility of further rounds of funding in the future. In order to be eligible, applicants must be based in Maine and already own a Class 3 to 7 vehicle in their fleet. The maximum award for different vehicle classes is shown in Table 8.

Vehicle Class	Maximum Award			
Class 3	40% of purchase price up to \$40,000			
Class 4	40% of purchase price up to \$60,000			
Class 5	50% of purchase price up to \$80,000			
Class 6	50% of purchase price up to \$100,000			
Class 7	50% of purchase price up to \$120,000			

TABLE 8 EFFICIENCY MAINE INCENTIVE LEVELS

Along with awards for vehicle purchases, the program also offers incentives for Level 2 charging and professional services such as consulting. For further information, and to apply, fleets should visit <u>the program website</u>.

RESULTS

Total Cost of Ownership

Calculating the total cost of ownership (TCO) for a vehicle offers fleet owners information to evaluate direct and indirect costs of EV purchases, as well as potential savings over the life cycle of purchased vehicles. The transition to EVs involves a shift in perspective regarding TCO components. Traditional internal combustion engine (ICE) vehicle costs are usually presented as capital cost for vehicles and dollar per gallon (\$/gal) costs for fuel, as well as lifetime maintenance expenses. An analysis of TCO for EVs must consider power output, \$ per kilowatt, grants and incentive programs, and planning and installing EVSE. While EVs are typically more expensive upfront, they are often less expensive to operate and maintain than comparable ICE vehicles; in many cases, these operational savings can offset higher upfront costs across the lifespan of the vehicle, resulting in a positive TCO.

TCO is calculated by combining the vehicle capital and operating costs over a set period of operations. For this analysis, the vehicle price points came from industry averages. Calculations assume a purchase in 2025 and a 12-year vehicle life, which is average across Maine trucks in this class. The results represent one vehicle in each duty cycle. Calculations accounted for the Efficiency Maine Trust vehicle incentives and the Federal Commercial Clean Vehicle tax credit. The results are estimates and actual cost differences may vary.

Each TCO scenario is modeled with a capital procurement cost for the diesel versus electric model and does not include any vehicle resale or residual values. The Federal tax credit is detailed in the <u>Federal Incentives</u> section and, along with Maine State incentives, is taken into consideration when modeling cumulative costs over time. For simplicity, the TCO calculation includes procurement of EVSE and infrastructure upgrades based on the cost of a single port. Infrastructure upgrade costs are calculated per location, not per vehicle. Those costs are modeled in the <u>Fueling/Charging Cost Analysis</u> section. The included costs are vehicle procurement, sales tax, Federal excise tax, maintenance, fuel, and insurance costs. Level 2 charging was assumed for Lynch Logistics' Ford Transit vans, Class 4 box trucks, and Class 6 straight trucks. Level 3 DC fast charging was assumed for their Class 7 and Class 8 trucks.

Ford Transit Van

Lynch Logistics' two Ford Transit vans have an average annual mileage of up to 25,000 miles and operate 260 days per year, meaning their daily driving distance is up to about 96 miles. Figure 17 shows cumulative costs over time and Figure 18 shows itemized total costs.

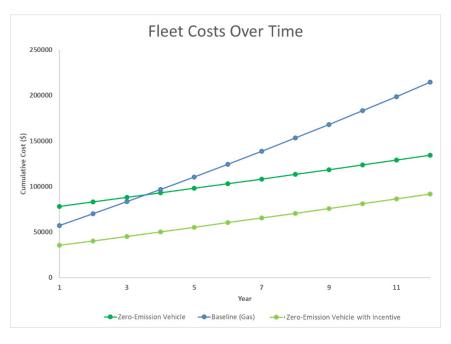

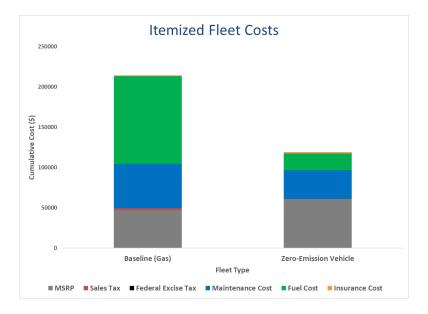

FIGURE 18 FORD TRANSIT VAN—ITEMIZED FLEET COSTS

This TCO analysis compares a gasoline-powered cargo van priced at \$47,000 with an electric cargo van priced at \$61,000. It assumes a \$3.50/gallon price of gasoline and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$12,200 for the costs of one Level 2 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$24,400 off the purchase vehicle price. The Commercial Clean Vehicle Tax Credit removes \$18,300 more (30 percent of the vehicle manufacturer's suggested retail price or MSRP), reducing the procurement cost further to \$34,729.

The results indicate that the cargo van's payback period is five years without the incentive and that the electric vehicle produces savings at the point of purchase with the incentive. The electric cargo van produce estimated annual fuel costs savings of 136 percent (\$6,321) and estimated annual maintenance costs savings of 42 percent (\$1,750), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts) Itemized costs are shown in Table 9.

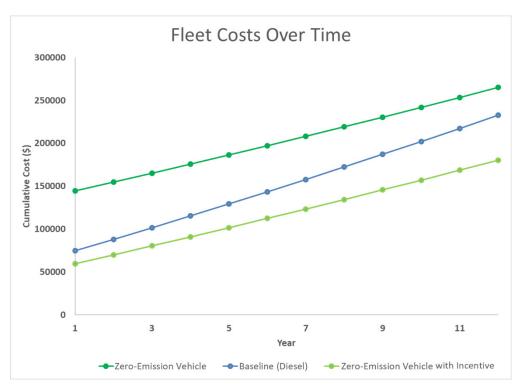

TABLE 9	FORD TRANSIT VAN ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
Manufacturer's Suggested Retail Price	\$47,000	\$61,000
Sales Tax	\$2,585	\$3,355
Federal Excise Tax	\$0	\$O
Maintenance Cost	\$26,400	\$17,160
Fuel Cost	\$52,150	\$9,936
Insurance Cost	\$1,227	1,592
Infrastructure Costs	\$0	\$12,200

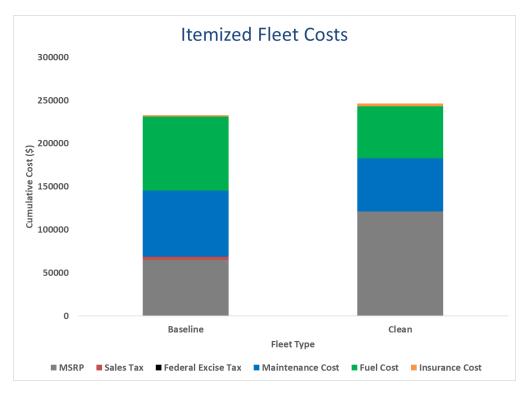

Chevy 4500 Box Truck

Lynch Logistics' Chevy 4500 box truck has an average annual mileage of up to 35,000 miles and operates 260 days per year, meaning its daily driving distance is up to about 135 miles. Figure 19 shows cumulative costs over time and Figure 20 shows itemized total costs.

This TCO analysis compares a diesel-powered box truck priced at \$65,000 with an electric box truck priced at \$121,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$12,200 for the costs of one Level 2 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$48,400 off the purchase vehicle price. The Commercial Clean Vehicle tax credit removes \$36,300 more (30 percent of the vehicle MSRP), reducing the procurement cost further to \$36,300.

The results indicate that the box truck does not reach cost parity without the incentive but that the electric vehicle produces savings at the point of purchase with the incentive. The electric box truck produces estimated annual fuel costs savings of 34 percent (\$1,788) and estimated annual maintenance costs savings of 22 percent (\$1,400), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 10.

 TABLE 10
 CHEVY 4500 BOX TRUCK ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
MSRP	\$65,000	\$121,000
Sales Tax	\$3,575	\$6,655
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$7,000	\$5,600
Fuel Cost	\$6,163	\$4,375
Insurance Cost	\$195	\$363
Infrastructure Costs	\$0	\$12,200

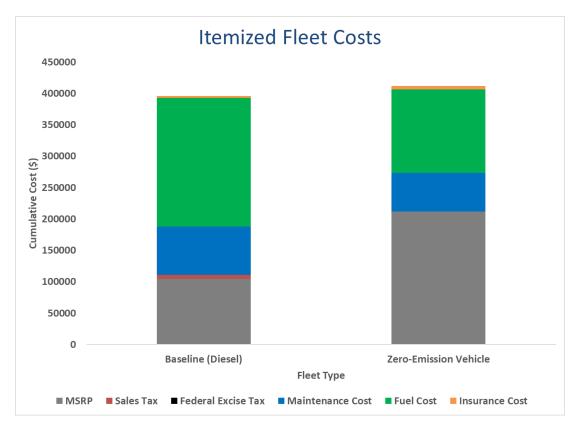

Class 6 Truck

Lynch Logistics' 13 Class 6 Freightliner M2106 have an average annual mileage of up to 35,000 miles and operate 260 days per year, meaning their daily driving distance is up to about 135 miles. Figure 21 shows cumulative costs over time and Figure 22 shows itemized total costs.

This TCO analysis compares a diesel-powered truck priced at \$105,000 with an electric truck priced at \$212,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$12,200 for the costs of one Level 2 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$100,000 off the purchase vehicle price. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$72,000.

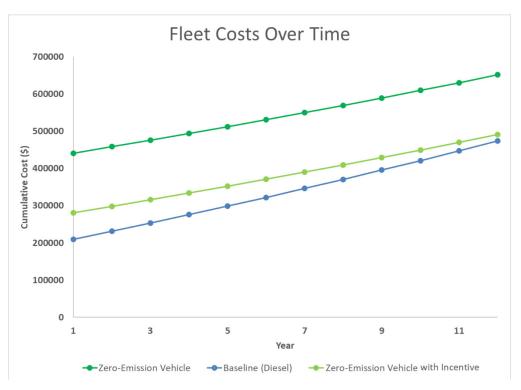

The results indicate that the Class 6 truck does not reach cost parity without the incentive but that the electric vehicle produces savings at the point of purchase with the incentive. The electric truck produces estimated annual fuel costs savings of 42 percent (\$5,140) and estimated annual maintenance costs savings of 22 percent (\$1,400), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 11.

Cost Components	Baseline	ZEV
MSRP	\$105,000	\$212,000
Sales Tax	\$5,775	\$11,660
Federal Excise Tax	\$0	\$0
Maintenance Cost	\$7,000	\$5,600
Fuel Cost	\$24,766	\$9,625
Insurance Cost	\$300	\$604
Infrastructure Costs	\$0	\$12,200

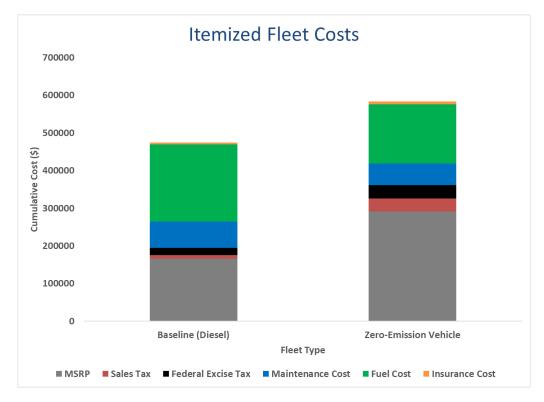

Class 7 Truck

Lynch Logistics' five Class 7 Freightliner M2106 have an average annual mileage of up to 35,000 miles and operate 260 days per year, meaning their daily driving distance is up to about 135 miles. Figure 23 shows cumulative costs over time and Figure 24 shows itemized total costs.

This TCO analysis compares a diesel-powered truck priced at \$166,000 with an electric truck priced at \$291,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$120,000 off the purchase vehicle price. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$130,000.

The results indicate that the Class 7 truck does not reach cost parity with or without the incentive, but there are still fuel and maintenance cost savings. The electric truck produces estimated annual fuel costs savings of 26 percent (\$3,390) and estimated annual maintenance costs savings of 18 percent (\$1,050), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 12.

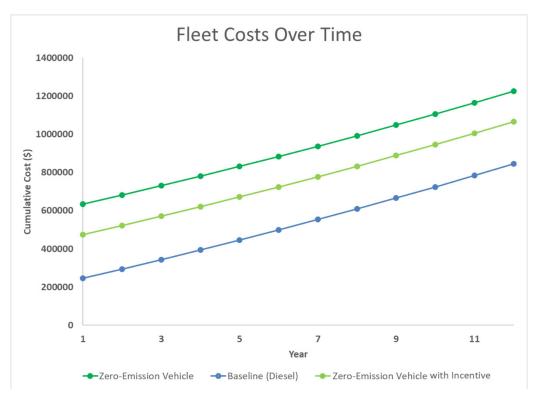

Cost Components	Baseline	ZEV
MSRP	\$166,000	\$291,000
Sales Tax	\$9,130	\$16,005
Federal Excise Tax	\$19,920	\$34,920
Maintenance Cost	\$6,300	\$5,250
Fuel Cost	\$14,766	\$11,375
Insurance Cost	\$473	\$829
Infrastructure Costs	\$0	\$87,050

TABLE 12 CLASS 7 ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

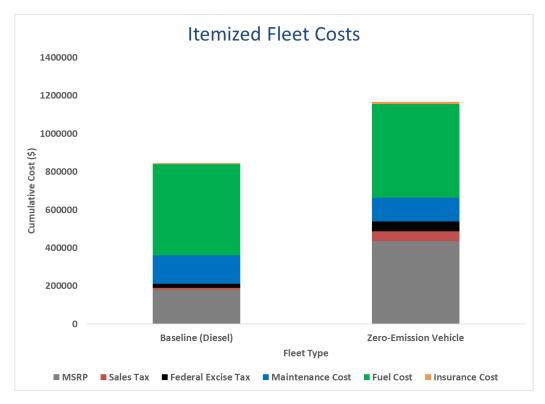

Class 8 Truck

Lynch Logistics' 30 Class 8 trucks—Freightliner 122SD, Freightliner Cascadia, and Western Star 49X—have an average annual mileage of up to 74,000 miles and operate 260 days per year, meaning their daily driving distance is up to about 285 miles. Figure 25 shows cumulative costs over time and Figure 26 shows itemized total costs.

This TCO analysis compares a diesel-powered truck priced at \$166,000 with an electric truck priced at \$291,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 charging port hardware, installation and local infrastructure, and utility-side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled Maine incentive is \$120,000 off the purchase vehicle price. The Commercial Clean Vehicle tax credit removes \$40,000 more, reducing the procurement cost further to \$130,000.

The results indicate that the Class 8 truck does not reach cost parity with or without the incentive, but there are still fuel and maintenance cost savings. The electric truck produces estimated annual fuel costs savings of 26 percent (\$3,390) and estimated annual maintenance costs savings of 18 percent (\$1,050), primarily due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 12.

Cost Components	Baseline	ZEV
MSRP	\$170,299	\$435,000
Sales Tax	\$10,644	\$27,188
Federal Excise Tax	\$20,435	\$52,200
Maintenance Cost	\$108,900	\$90,750
Fuel Cost	\$358,937	\$236,973
Insurance Cost	\$4,445	\$11,354
Infrastructure Costs	\$0	\$87,050

Fleet Emissions

Maine's transportation sector is the largest source of greenhouse emissions in the State, and medium- and heavy-duty trucks account for 27 percent of these emissions.¹ Providing power to vehicles via electricity is significantly less polluting than diesel fuel, especially in areas served by low-carbon sources of electricity generation. Renewable resources powered

¹ Rocky Mountain Institute. "<u>RMI Analysis: With Smart Policy, Truck Electrification Is Within Reach</u>." Accessed October 2024.

64 percent of Maine's total electricity net generation, and wind provided the largest share at 23 percent of the State's total net generation, in 2022.²

An analysis of Fleet 2's direct exhaust emissions was performed using the U.S. Environmental Protection Agency's Diesel Emission Quantifier tool. The analysis combines the average annual mileage traveled by all 97 vehicles in the fleet. Converting Fleet 2's vehicles to ZEVs would eliminate all of these direct emissions.

TABLE 14 INTERNAL COMBUSTION ENGINE FLEET EMISSIONS

Pollutant	Annual Emissions (Short Tons/Year)
Carbon Monoxide (CO)	13.06
Nitrogen Oxides (NO _x)	19.285
Particulate Matter (PM)	0.034
Carbon Dioxide (CO ₂)	5,909

IMPLEMENTATION CONSIDERATIONS

Energy Storage and Resiliency

Power outages are always a possibility at fleet depots, regardless of grid advancements and fidelity. Fleets should consider contingencies for maintaining operations of electric trucks in the event of a long-term power outage. Today's electric vehicles do not necessarily require electricity from the grid to be available to properly fuel. There are means of fueling battery-electric vehicles using energy storage solutions, most commonly batteries, which are safer than storing flammable fossil fuels on site. Critical vehicle operations may consider other forms of backup power to ensure charging access, including generators.

Many consumers have asked whether EVs can be used in an emergency to provide backup power to homes, offices, and other facilities. For a vehicle to provide backup power, there are several additional considerations: whether the vehicle is designed for 'bidirectional charging', meaning that the vehicle can output power, and whether the facility has appropriate two-way charging equipment. The Ford F-150 Lightning is equipped to support bidirectional charging, and Ford supports claims that the truck can provide up to 100 kWh of

² U.S. Energy Information Administration. <u>State Profile and Energy Estimates</u>. Accessed October 2024.

power on a single charge, which is enough to power an average house for three days (30 kWh per day).

Preheat/Precool

One consideration often overlooked in commercial EV operation is the energy use associated with climate control, either for the operator or for the goods themselves. Idle time spent bringing a cab to a comfortable riding temperature uses energy otherwise intended for moving the vehicle along its intended route. The energy used to heat or cool the vehicle cabin may consume a significant amount of the vehicle's battery capacity. Preconditioning while vehicles are connected to chargers at the depot is a simple approach to providing comfortable conditions and extending driving range during winter and summer. These types of considerations are important to factor in, and experiment with, during a fleet's initial deployment.

"Vampire" Energy

Vehicles of all kinds are meant to be driven; they benefit from regular usage by foregoing the potential negative impacts of remaining idle for extended periods. One such impact to commercial EVs is what is known as "vampire" energy, where a vehicle's battery will slowly deplete while it remains unplugged and idle. This is normal behavior and not an indication that anything is malfunctioning. Rather, this is an expected effect resulting from a combination of onboard electronics that remain on or in stand-by, as well as the natural chemical reactions occurring in a vehicle's battery.

Best practices for long-term battery health include keeping a vehicle's battery charged to 80 percent when possible and taking measures to ensure its state of charge does not regularly fall below 20 percent while idle. Managed and networked charging infrastructure can help fleets keep battery state of charge within this optimal range. For smaller EV deployments and fleets involving just a few vehicles, this also may be achievable through effective training and communication with staff on-site.

REFERENCES

CALSTART's Zero-Emission Technology Inventory (ZETI) is a public online interactive dashboard containing the status and anticipated timing of commercial availability for zero-emission MHDVs across a range of vehicle platforms and key global regions. ZETI was the primary tool used to find equivalent medium and heavy-duty electric vehicle models that could replace the current fleet inventory.

SUMMARY

Fleet 3 is a retail goods delivery freight fleet serving the State of Maine. The fleet has two warehouses: Warehouse 1 in Penobscot County with seven tractor trailers and Warehouse 2 in Aroostook County with two tractor trailers. Both electric and hydrogen fuel cell replacement recommendations are provided for Fleet 3's tractor trailers.¹

The trailers based in Warehouse 1 travel approximately 220 miles per day and return to a depot overnight. These travel patterns and overnight dwell times are well-suited to electric or hydrogen vehicles and transitioning to these zero-emission alternatives would result in immediate fuel and maintenance cost savings. Despite that, a zero-emission replacement is not projected to produce lifetime savings due to high upfront capital costs for electric and hydrogen trucks.

The trailers based in Warehouse 2 travel approximately 560 miles per day. A zero-emission replacement would be projected to produce lifetime savings for this duty cycle starting in the 9th year; however, these vehicles would need to be charged along their route, which may not be feasible or cost-effective at this time. Alternatively, Fleet 3 could consider hydrogen fuel cell vehicles where longer ranges are available; more significant fueling station infrastructure challenges exist at this time.

INTRODUCTION

The Maine Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles ("roadmap") charts a path for Maine to decarbonize the trucks and buses moving people and goods within and through the state. As part of the roadmap, the project team has conducted a series of case studies with Maine businesses to identify real world opportunities and challenges for fleet electrification. The case studies are intended to 1) serve the participating fleets by providing customized fleet electrification assessments; and 2) augment the roadmap by evaluating electrification use cases, total cost of ownership, and barriers in the context of actual Maine business operations.

¹ Fleet 3 additionally has a fleet of delivery box trucks, which are not included in this analysis.

Fleet Information

Fleet 3 operates seven tractor trailers out of Warehouse 1 in Penobscot County, ME and two tractor trailers out of Warehouse 2 in Aroostook County, ME. These trucks are used for delivering retail goods. Trucks based at Warehouse 2 also transport goods between warehouses overnight. Table 1 provides an inventory of Fleet 3's vehicles.

Vehicle Group	Vehicle Quantity	Vehicle Class	Fuel Type	Manufacturing Year (average)	Average Annual Miles	Owned or Leased Vehicles
Class A Tractor	7	Class 8–Over 33,000 lbs.	Diesel	2022	55,000	Owned
Class A Tractor	2	Class 8–Over 33,000 lbs.	Diesel	2021	140,000	Leased

Vehicle Recommendations

To adequately define the needs of a fleet, the vehicles used are categorized into duty cycles. Duty cycles are classifications that describe both the vehicle, by type and class, and *how it is operated*, including typical miles traveled, type of use (local versus highway), and fuel consumption.

Vehicle recommendations are not exhaustive of all options that may be on the market; selections are included based on those most likely to meet Fleet 3's duty cycles.

Fleet 3 operates seven trailers out of Warehouse 1 that drive an average of 220 miles per day and dwell for 11.5 hours overnight and two trailers out of Warehouse 2 that drive an average of 560 miles per day and dwell for three hours overnight.

The recommended electric trailers in Table 2 represent the high-end of ranges available on the market. The vehicles at Warehouse 2 can be charged using DC fast charging during their three-hour dwell time. For routes over the maximum range, Fleet 3 can take advantage of public DC fast chargers along their routes to quickly recharge. This is explained further in the Charging and Infrastructure section.

Alternatively, Fleet 3 can explore the hydrogen fuel cell options listed in Table 3. Hydrogen fuel cells allow for faster refueling and longer ranges in some cases. Fuel cell vehicles require

a source of hydrogen for refueling, which could be either privately or publicly owned. The U.S. Department of Energy (DOE) has awarded projects to expand a nationwide hydrogen refueling corridor, however the capital to install and run a hydrogen refueling station is significant, in the million-dollar range. Many fleets could benefit from public hydrogen stations, paying for the fuel but not the infrastructure.

CHARGING AND INFRASTRUCTURE

Fleet Electrification Overview

Fleet electrification involves coordination between the fleet and their electric utility, contractors, developers, vehicle original equipment manufacturers, and electric vehicle service providers to determine the power, quantity, and arrangement of electric vehicle supply equipment (EVSE), or vehicle charging, for a particular site. Once vehicle quantity and duty cycles are defined, the quantity and power of EVSE needed can be determined. In most fleet charging configurations, it is typical to install one dedicated charging plug per electric vehicle (EV). This is to support overnight charging, when electricity rates are low and vehicles are ordinarily not in operation; overnight charging typically lends itself to less costly EVSE due to the lower power usage required to charge a vehicle over a long dwell time. For use cases with higher energy needs and/or less available dwell time for charging, higher-power chargers may be required to meet the energy needs of EVs.

Regardless of the quantity or power of charging equipment, it is important to keep in mind the additional space necessary for charging dispensers, transformers, and other considerations which may change a site's traffic pattern or "flow."

It is recommended that any chargers installed are networked, which means they include the capability to communicate over cellular networks. Most businesses choose to install networked chargers, due to access control, ensuring that only the fleet's service vehicles can charge at these chargers. Alternatively, fleets can install "behind the fence" non-networked charging in a secure location only accessible to fleet vehicles, assuring the same charging restrictions and availability. However, networked chargers can provide a bevy of technical information, including duration of charge and charge rate, useful for operational planning and decision- making.

Inductive (wireless) charging equipment, which uses an electromagnetic field to transfer electricity to an EV without a cord, is now commercially available as an aftermarket add-on, and has the potential to support rapid medium- and heavy-duty vehicle (MHDV) charging at depots and in warehouse environments where trucks park for extended periods of time, such as loading bays. Spreading a charging schedule across as many hours as possible will often lead to the lowest capital and operational cost; thus, it is important to weigh various charging solutions against business needs. The next section describes in greater detail some solutions for how this can be addressed.

Charging Equipment

EV charging equipment is classified by battery charging rates. Time to charge will vary depending on battery state of charge, total energy storage, the type of battery, and the type of charging equipment. Charging time can range from less than 20 minutes to 20 hours or more, depending on these factors.

There are three types of charging: Level 1, Level 2, and Level 3 (direct current or DC fast). Level 1 charging is the slowest method and uses a standard alternating current (AC) wall outlet. It adds 2 to 5 miles of range per hour of charging. Because of its slow rate, Level 1 charging is typically only used at home for personal vehicles or workplaces. Level 2 is another AC method that is significantly faster than Level 1. Level 2 is the most common method of charging as it allows most light- and medium-duty vehicles to charge overnight while also being significantly cheaper and easier to install than Level 3 chargers. Level 2 chargers are most commonly found serving commercial vehicles and in public places like parking garages, shopping centers, and tourist attractions. Level 3 DC fast charging is the fastest method of charging, but also the most expensive for both the charger and infrastructure required. These chargers are typically only recommended for heavy-duty trucks and vehicles that dwell for a few hours or less.

Across the United States, there are four major plug types: J1772 ("J-plug"), Tesla (also known as North American Charging Standard or NACS, or SAE J3400), CHAdeMO, and CCS.

- » The J1772 standard is used for Level 1 and 2 AC charging.
- » Tesla is used for Level 2 and 3.
- » CHAdeMO and CCS are used primarily for Level 3 DC fast charging.

While other proprietary plugs exist for MHDVs, these four represent the majority of those in use. The U.S. Department of Transportation National Electric Vehicle Infrastructure (NEVI) Program has standardized federally funded plugs across Level 2 and Level 3 charging, helping build out a national network of publicly-available charging equipment with predictable plug configurations.

In 2022, Tesla opened its previously proprietary charging standard to other EV manufacturers. In the coming years, its NACS will become the most prevalent charger connection. This connector is also referenced as SAE J3400. All connector types are shown below in Figure 1, but fleets should anticipate a growing share of vehicle options to utilize the NACS standard.

Industry leaders have introduced the concept of the Megawatt Charging Solution, designed to provide higher levels of power needed by MHDVs over a shorter period of charging time. Megawatt chargers require significant infrastructure investment (1–3 million volt-amperes or MVA) and may allow for faster adoption of EVs for long-haul trucking. However, most local and regional delivery businesses can be supported by Level 2 or DC fast chargers.

Туре	Level 1 Charging	Level 2 Charging	Level 3 DC Fast Charging	Megawatt
Connector	J1772	J1772 Tesla/ NACS/ SAE J3400	CHAdemo CCS Tesla/ NACS/ SAE J3400	MCS
Voltage	120 V AC	208–240 V AC	400 V-1000 V DC	1–3 kV A
Power Output	1 kW	7 kW–19 kW	50–350 kW	900 kW+

FIGURE 1 TYPES OF CHARGERS

Managed Charging

Energy management can greatly decrease operational costs associated with fleet electrification. Managed charging, sometimes called "smart charging," entails the purchase and use of EVSE that can actively track and modulate charging, and a subscription for energy management software provided by the EVSE manufacturer or network provider to keep consumption levels within a predetermined range. While there are additional up-front and monthly costs associated with these technologies, their long-term benefits should also be considered from a total cost of ownership perspective. Depending on the design of local electricity rates, electricity pricing can be based upon the time of day during which electricity is used, where marginal pricing is greater during times of high demand and lower when strain to the grid is at its lowest. Fleets may also be exposed to demand charges, which are increased electricity chargers incurred from large, simultaneous power draws—such as when multiple heavy-duty trucks plug into fast charging at the same location at the same time. However, charging when electricity costs are lowest is not always feasible or operationally convenient for fleets. Managed charging software automates charging to coincide with dwell times while enabling fleets to benefit from lower electric rates and/or mitigating demand charges.

Fleet 3 could utilize managed charging at Warehouse 1 where their vehicles have extended downtime. This could allow them to charge the vehicles using less equipment rather than procuring one charging port per vehicle.

On-Route versus Depot Charging

Most commercial EV deployments currently in operation rely solely on depot charging, or a "return-to-base" schedule where a fleet keeps vehicles parked at one location owned/ leased by the organization operating those vehicles. While policy efforts and Federal funding are advancing the development of strategically sited on-route fast charging and public charging hubs, it is recommended that current EV deployments plan for on-site depot charging, where feasible.

The Alternative Fuels Database, provided by the U.S. DOE, includes a <u>tool</u> to find publicly available charging stations, as does the similar <u>PlugShare</u> tool. Users can also map a route, similar to Google Maps, and see all charging stations along the route. These tools compile data from many networks of charging stations, such as <u>ChargePoint</u>, <u>Electrify America</u>, <u>EVgo</u>, and <u>Tesla</u>. By clicking on a charging station, one can view the number of available charging ports, as well as the type of charging connector.

It is important to note that not all charging stations listed on these sites will be appropriate for charging MHDVs. Most Class 2b and Class 3 vehicles will be able to use charging stations designed for light-duty vehicles, but Class 4–8 vehicles are often too large for typical light-duty vehicle parking spaces, and may require higher power levels to recharge quickly. It is anticipated that most public charging stations for medium- and heavy-duty trucks will require power levels of 150–350kW or more per port, paired with pull-through charging stalls and

ample clearance. These may not be available at stations that appear in the DOE or PlugShare tools.

Few DC fast chargers are currently available on-route, and those that do exist may not be able to accommodate a Class 8 truck. The network of available chargers will continue to grow, however; active chargers and hours of operation are updated in these tools on a monthly basis. An example charger that would be convenient for Fleet 3 is shown in Figure 2.

Public chargers such as ChargePoint or EVgo typically require that drivers use a mobile application to interact with the charger and pay for their charge, either through the app itself, or with a credit card at the charger. In 2023, the NEVI program introduced standards for future EVSE installation including provisions that stations must implement non-proprietary charging ports, accept open-access payments such as pay by phone or contactless credit/ debit card, be located along designated FHWA <u>Alternative Fuel Corridors</u>, and be publicly available.

Fueling/Charging Cost Analysis

A charging analysis was performed for electrification scenarios for Fleet 3 using CALSTART's Charging Infrastructure Optimization (CHARIOT) Tool. The CHARIOT tool aims to optimize Fleet 3's charging schedule, to find a schedule that works well with fleet operations while achieving lowest possible energy cost. It also provides a projected energy flow of a fleet's energy consumption and, when applicable, potential for on-site energy generation (e.g., solar power with battery storage) to get a sense of a site's energy independence and grid reliance. Fleet 3's electricity is provided by Versant.

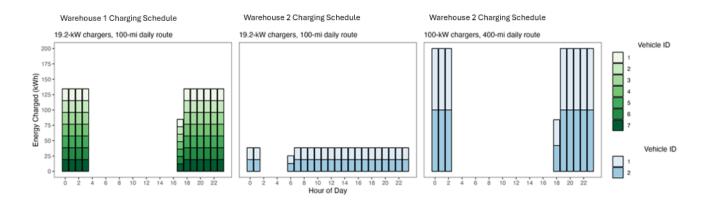

The CHARIOT tool was used twice for each warehouse: once using Versant's high peak timeof-use (TOU) rate (\$3.55/kWh) and once using a flat TOU rate (\$0.12/kWh).

Daily Charging Load Profiles

Load calculations were performed for Warehouse 1 and Warehouse 2. Due to the higher mileage of the two tractor trailers at Warehouse 2, a higher mileage scenario of 400 miles with a 100-kW Level 3 DC fast charger was included along with the 100 miles and a 19.2-kW level 2 scenario for both Warehouse 1 and 2. Figure 3 shows the daily charging load profiles for all vehicles for the three scenarios.

Although Level 2 charging was modeled for both sites, the Class 8 truck models listed above may not be compatible with Level 2 charging, and Fleet 3 should plan to charge using DC fast chargers. All vehicles with a 100 mile duty cycle can be charged within 3 hours at their domicile location using DC fast chargers. Figure 3 shows what daily charging profiles (energy demand by hour) might look like for this fleet.

FIGURE 3 DAILY CHARGING LOAD PROFILES—ALL VEHICLES

Based on the anticipated energy needs of two electric tractors at Warehouse 2 compared to two diesel tractors, Fleet 3 would be estimated to achieve significant reductions to their annual energy costs. Total annual energy cost and cost per mile for diesel versus electric vehicles operating out of Warehouse 2 are shown in Figure 4 and Figure 5, respectively for a flat time-of-use rate scenario. Because of the reduced cost of charging compared to diesel fuel, Fleet 3 could expect a significantly decreased cost per mile of operation.

EVSE FINANCING

Federal Incentives

Commercial Clean Vehicle Tax Credit

The Federal Government's adoption of the Infrastructure Reduction Act (IRA) enacted new Federal tax credits (IRC Section 45W) for commercial clean (electric or hydrogen fuel cell) vehicles in 2022. Eligible entities include businesses and tax-exempt organizations that purchase commercial clean vehicles between January 1, 2023, and before January 1, 2033. Heavy-duty vehicles with a gross vehicle weight rating of 14,000 lbs. or greater are eligible for a tax credit up to \$40,000, or 30 percent of the incremental cost of the vehicle as compared to a gasoline or diesel vehicle, whichever is lower. Applicable electric vehicles must have a battery with at least 15 kWh of capacity and be made by a qualified manufacturer (see the IRS's list for examples). For tax exempt entities, such as schools, governments, or non-profit organizations, the tax credit is available through a mechanism commonly known as direct, or elective, pay.

Alternative Fuel Infrastructure Tax Credit

Beginning on January 1, 2023, installation of EV charging equipment is eligible for a tax credit of 30 percent of the installation costs (or 6 percent in the case of property subject to depreciation), not to exceed \$100,000. Permitting and inspection fees are not included in covered expenses. As above, tax-exempt entities are eligible to claim these credits through direct or elective pay.

These tax credits are only available to business locations and tax-exempt entities with the following census tract requirements:

- » A population census tract where the poverty rate is at least 20 percent.
- » Metropolitan and non-metropolitan area census tract where the median family income is less than 80 percent of the State median family income level.

Fleets should work with their charging infrastructure installers to determine eligibility by identifying their census tract using <u>this tool</u> and determining if it is included in the <u>IRS's list</u>. If eligible, <u>tax form 8911</u> should be completed.

State Incentives

Efficiency Maine Medium- and Heavy-Duty Vehicle Incentive Pilot

In October 2024, the quasi-state agency Efficiency Maine Trust launched a pilot program to demonstrate potential use cases and performance of zero-emission MHDVs in Maine. Awards will be issued in three rounds, with applications open through the end of February 2025, with the possibility of further rounds of funding in the future. In order to be eligible, applicants must be based in Maine and already own a Class 3 to 7 vehicle in their fleet. The maximum award for different vehicle classes is shown in Table 3.

Vehicle Class	Maximum Award
Class 3	40% of purchase price up to \$40,000
Class 4	40% of purchase price up to \$60,000
Class 5	50% of purchase price up to \$80,000
Class 6	50% of purchase price up to \$100,000
Class 7	50% of purchase price up to \$120,000

TABLE 3 EFFICIENCY MAINE INCENTIVE LEVELS

Along with awards for vehicle purchases, the program also offers incentives for Level 2 charging and professional services such as consulting. For further information, and to apply, fleets should visit <u>the program website</u>.

RESULTS

Total Cost of Ownership

Calculating the total cost of ownership (TCO) for a vehicle offers fleet owners information to evaluate direct and indirect costs of EV purchases, as well as potential savings over the life cycle of purchased vehicles. The transition to EVs involves a shift in perspective regarding TCO components. Traditional internal combustion engine (ICE) vehicle costs are usually presented as capital cost for vehicles and dollar per gallon (\$/gal) costs for fuel, as well as lifetime maintenance expenses. An analysis of TCO for EVs must consider power output, \$ per kilowatt, grants and incentive programs, and planning and installing EVSE. While EVs are typically more expensive upfront, they are often less expensive to operate and maintain than comparable ICE vehicles; in many cases, these operational savings can offset higher upfront costs across the lifespan of the vehicle, resulting in a positive TCO.

TCO is calculated by combining the vehicle capital and operating costs over a set period of operations. For this analysis, the vehicle price points came from industry averages. Calculations assume a purchase in 2025 and a 12-year vehicle life, which is average across Maine trucks in this class. The results represent one vehicle in each duty cycle. Calculations accounted for the Efficiency Maine Trust vehicle incentives and the Federal Commercial Clean Vehicle tax credit. The results are estimates and actual cost differences may vary.

Each TCO scenario is modeled with a capital procurement cost for the diesel versus electric model and does not include any vehicle resale or residual values. The Federal tax credit is detailed in the <u>Federal Incentives</u> section and, along with Maine state incentives, is taken into consideration when modeling cumulative costs over time. For simplicity, the TCO calculation includes procurement of EVSE and infrastructure upgrades based on the cost of a single port. Infrastructure upgrade costs are calculated per location, not per vehicle. Those costs are modeled in the <u>Fueling/Charging Cost Analysis</u> section. The included costs are vehicle procurement, sales tax, Federal excise tax, maintenance, fuel, and insurance costs.

Tractor Trailor—Warehouse 1

Fleet 3's seven Class 8 tractor trailers at Warehouse 1 have an average annual mileage of 55,000 miles and operate an average of 250 days per year, meaning their daily driving distance is about 220 miles. Figure 6 shows cumulative costs over time and Figure 7 shows itemized total costs.

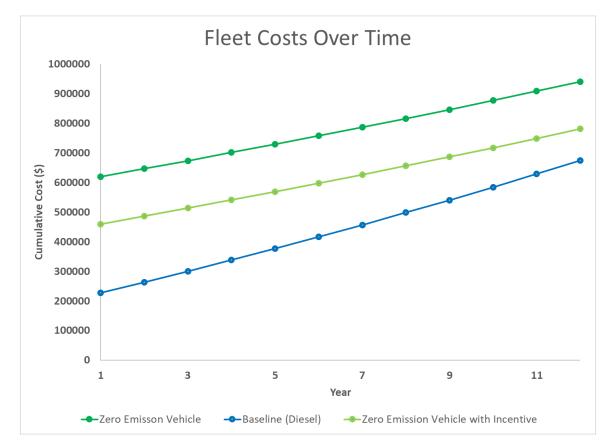

FIGURE 6 TRACTOR TRAILER WAREHOUSE 1—FLEET COSTS OVER TIME

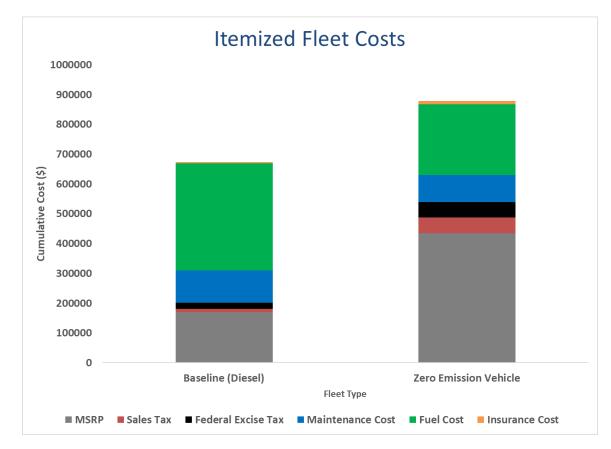

FIGURE 7 TRACTOR TRAILER WAREHOUSE 1—ITEMIZED FLEET COSTS

This TCO analysis compares a Class 8 diesel-powered tractor trailer priced at \$170,300 with an electric tractor trailer priced at \$435,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 DC fast charging port hardware, installation and local infrastructure, and utility side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled incentive is \$120,000 off the vehicle purchase price, reducing the capital procurement cost to \$315,000. The Commercial Clean Vehicle Tax Credit removes \$40,000 more (30 percent of the manufacturer's suggested retail price or MSRP, capped at \$40,000), reducing the procurement cost further to \$275,000.

The results indicated that the tractor trailer's payback period exceeds its expected life with and without incentives included due to higher upfront capital costs. The electric tractor trailer still produces an estimated 39 percent reduction in annual fuel costs (\$8,361) and an estimated 18 percent reduction in annual maintenance costs (\$1,650). Itemized costs are shown in Table 4.

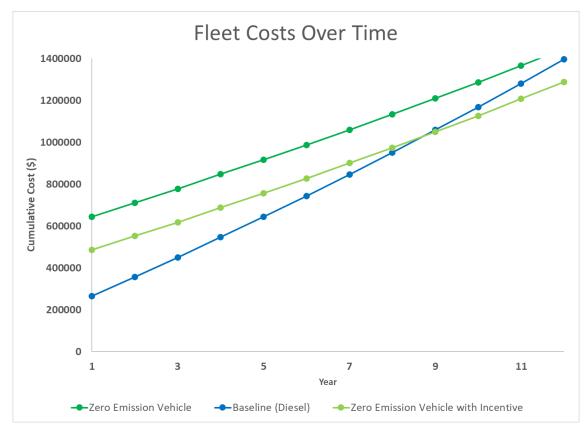

TABLE 4 CLASS 8 TRACTOR TRAILER ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Cost Components	Baseline	ZEV
Manufacturer's Suggested Retail Price	\$170,299	\$435,000
Sales Tax	\$10,644	\$27,188
Federal Excise Tax	\$20,436	\$52,200
Maintenance Cost	\$108,900	\$90,750
Fuel Cost	\$358,938	\$236,973
Insurance Cost	\$4,445	\$11,354
Infrastructure Costs	\$0	\$87,050

Tractor Trailor—Warehouse 2

Fleet 3's two tractor trailers at Warehouse 2 have an average annual mileage of 140,000 miles and operate an average of 250 days per year, meaning their daily driving distance is about 560 miles. Figure 8 shows cumulative costs over time and Figure 9 shows itemized total costs.

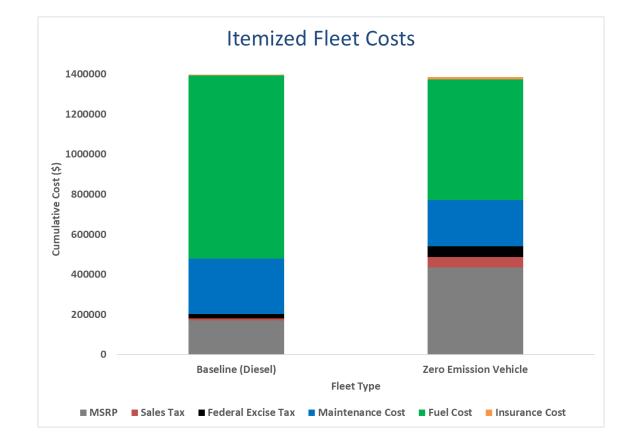

FIGURE 9 TRACTOR TRAILER WAREHOUSE 2—ITEMIZED FLEET COSTS

This TCO analysis compares a Class 8 diesel-powered tractor trailer priced at \$170,300 with an electric tractor trailer priced at \$435,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 DC fast charging port hardware, installation and local infrastructure, and utility side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled incentive is \$120,000 off the purchase vehicle price, reducing the capital procurement cost to \$315,000. The Commercial Clean Vehicle Tax Credit removes \$40,000 more (30 percent of the MSRP capped at \$40,000), reducing the procurement cost further to \$275,000.

The results indicated that the tractor trailer reaches cost parity in the 9th year after purchase. The electric tractor trailer produces an estimated 39 percent reduction in annual fuel costs (\$21,283) and an estimated 18 percent in annual maintenance costs (\$4,200). Itemized costs are shown in Table 5.

Cost Components	Baseline	ZEV
MSRP	\$170,299	\$435,000
Sales Tax	\$10,644	\$27,188
Federal Excise Tax	\$20,436	\$52,200
Maintenance Cost	\$277,200	\$231,000
Fuel Cost	\$913,659	\$603,204
Insurance Cost	\$4,445	\$11,354
Infrastructure Costs	\$O	\$87,050

TABLE 5 CLASS 8 TRACTOR TRAILER ITEMIZED CUMULATIVE COSTS OVER 12 YEAR VEHICLE LIFE

Fleet Emissions

Maine's transportation sector is the largest source of greenhouse emissions in the State, and medium- and heavy-duty trucks account for 27 percent of these emissions.² Providing power to vehicles via electricity is significantly less polluting than diesel fuel, especially in areas served by low-carbon sources of electricity generation. Renewable resources powered 64 percent of Maine's total electricity net generation, and wind provided the largest share at 23 percent of the State's total net generation, in 2022.³

An analysis of Fleet 3's direct exhaust emissions was performed using the U.S. Environmental Protection Agency's Diesel Emission Quantifier tool. The analysis combines the average annual mileage traveled by all nine vehicles in the fleet. Converting Fleet 3's vehicles to ZEVs would eliminate all of these direct emissions.

TABLE 6 INTERNAL COMBUSTION ENGINE FLEET EMISSIONS

Pollutant	Annual Emissions (Short Tons/Year)	10-year Emissions (Short Tons)
Carbon Monoxide (CO)	1.322	13.22
Nitrogen Oxides (NOx)	1.510	15.1
Particulate Matter (PM)	0.002	0.02
Carbon Dioxide (CO2)	2,323	23,228

IMPLEMENTATION CONSIDERATIONS

Energy Storage and Resiliency

Power outages are always a possibility at fleet depots, regardless of grid advancements and fidelity. Fleets should consider contingencies for maintaining operations of electric trucks in the event of a long-term power outage. Today's electric vehicles do not necessarily require electricity from the grid to be available to properly fuel. There are means of fueling battery-electric vehicles using energy storage solutions, most commonly batteries, which are safer than storing flammable fossil fuels on site. Critical vehicle operations may consider other forms of backup power to ensure charging access, including generators.

Many consumers have asked whether EVs can be used in an emergency to provide backup power to homes, offices, and other facilities. For a vehicle to provide backup power, there are several additional considerations: whether the vehicle is designed for 'bidirectional charging', meaning that the vehicle can output power, and whether the facility has appropriate two-way charging equipment. The Ford F-150 Lightning is equipped to support bidirectional charging, and Ford supports claims that the truck can provide up to 100 kWh of power on a single charge, which is enough to power an average house for three days (30 kWh per day).

Preheat/Precool

One consideration often overlooked in commercial EV operation is the energy use associated with climate control, either for the operator or for the goods themselves. Idle time spent bringing a cab to a comfortable riding temperature uses energy otherwise intended for moving the vehicle along its intended route. The energy used to heat or cool the vehicle cabin may consume a significant amount of the vehicle's battery capacity. Preconditioning while vehicles are connected to chargers at the depot is a simple approach to providing comfortable conditions and extending driving range during winter and summer. These types of considerations are important to factor in, and experiment with, during a fleet's initial deployment.

"Vampire" Energy

Vehicles of all kinds are meant to be driven; they benefit from regular usage by foregoing the potential negative impacts of remaining idle for extended periods. One such impact to commercial EVs is what is known as "vampire" energy, where a vehicle's battery will slowly deplete while it remains unplugged and idle. This is normal behavior and not an indication that anything is malfunctioning. Rather, this is an expected effect resulting from a combination of onboard electronics that remain on or in stand-by, as well as the natural chemical reactions occurring in a vehicle's battery.

Best practices for long-term battery health include keeping a vehicle's battery charged to 80 percent when possible and taking measures to ensure its state of charge does not regularly fall below 20 percent while idle. Managed and networked charging infrastructure can help fleets keep battery state of charge within this optimal range. For smaller EV deployments and fleets involving just a few vehicles, this also may be achievable through effective training and communication with staff on-site.

REFERENCES

CALSTART's Zero-Emission Technology Inventory (ZETI) is a public online interactive dashboard containing the status and anticipated timing of commercial availability for zero-emission MHDVs across a range of vehicle platforms and key global regions. ZETI was the primary tool used to find equivalent medium and heavy-duty electric vehicle models that could replace the current fleet inventory.

SUMMARY

Fleet 4 is a retail goods delivery business that has central warehousing and makes retail deliveries statewide. The vehicles domicile at a southern Maine warehouse, including 97 Class 8 heavy-duty cabs, tractors, and sleepers.

The Class 8 cabs and sleepers performing retail delivery travel approximately 244 miles per day and do not have a precise domicile schedule, though it was estimated to be from 5 p.m. to 6 a.m. The warehouse also uses five yard tractors to switch trailers, operating approximately 55 miles per day. These travel patterns and overnight dwell times are wellsuited to electric vehicles. These vehicles could be charged fully within a dwell time of three hours using Level 3 DC fast chargers, and transitioning to these zero-emission alternatives would result in immediate fuel and maintenance cost savings. Despite that, a zero-emission replacement is not projected to produce lifetime savings due to high upfront capital costs for electric trucks.

INTRODUCTION

The Maine Clean Transportation Roadmap for Medium- and Heavy-Duty Vehicles ("roadmap") charts a path for Maine to decarbonize the trucks and buses moving people and goods within and through the State. As part of the roadmap, the project team has conducted a series of case studies with Maine businesses to identify real world opportunities and challenges for fleet electrification. The case studies are intended to 1) serve the participating fleets by providing customized fleet electrification assessments; and 2) augment the roadmap by evaluating electrification use cases, total cost of ownership, and barriers in the context of actual Maine business operations.

Fleet Information

Fleet 4 operates 92 cabs out of their warehouse in southern Maine. These trucks are used for delivery from the warehouse to retail locations. The five yard tractors which are part of the fleet are used to switch trailers out. Table 1 provides an inventory of Fleet 4's vehicles.

Vehicle Group	Vehicle Quantity	Vehicle Class	Fuel Type	Manufacturing Year (average)	Average Annual Miles	Owned or Leased Vehicles
Volvo Day Cab (owned)	48	Class 8–Over 33,000 lbs.	Diesel	2020	99,469	Owned
Volvo Day Cab (leased)	30	Class 8–Over 33,000 lbs.	Diesel	2022	90,426	Leased
Mack 64T Sleeper	9	Class 8–Over 33,000 lbs.	Diesel	2019	99,011	Owned
Peterbilt Day Cab	5	Class 8–Over 33,000 lbs.	Diesel	2023	67,315	Leased
Yard Tractor	5	Class 8–Over 33,000 lbs.	Diesel	2019	20,000	Owned

TABLE 1 FLEET 4 VEHICLE INVENTORY

Vehicle Recommendations

To adequately define the needs of a fleet, the vehicles used are categorized into duty cycles. Duty cycles are classifications that describe both the *vehicle*, by type and class, and *how it is operated*, including typical miles traveled, type of use (local versus highway), and fuel consumption.

Vehicle recommendations are not exhaustive of all options that may be on the market; selections are included based on those most likely to meet Fleet 4's duty cycles.

Class 8 Day Cabs and Trailers

Fleet 4 operates 83 day cabs out of their southern Maine warehouse that drive an average of 258 miles per day and dwell for approximately 12 hours overnight. For longer deliveries, they operate five sleeper cabs which drive an average of 271 miles per day and are estimated to domicile for 12 hours overnight.

The recommended electric tractor trailers in Table 2 represent the high-end of ranges available on the market. These vehicles can meet the majority of the warehouse vehicles' duty cycle with overnight Level 2 charging. If needed, they can be charged using DC fast charging during irregular dwell times. For routes over the maximum range, fleet 4 can take advantage of public DC fast chargers along their routes to quickly recharge. This is explained further in the Charging and Infrastructure section.

CHARGING AND INFRASTRUCTURE

Fleet Electrification Overview

Fleet electrification involves coordination between the fleet and their electric utility, contractors, developers, vehicle original equipment manufacturers, and electric vehicle service providers to determine the power, quantity, and arrangement of electric vehicle supply equipment (EVSE), or vehicle charging, for a particular site. Once vehicle quantity and duty cycles are defined, the quantity and power of EVSE needed can be determined. In most fleet charging configurations, it is typical to install one dedicated charging plug per electric vehicle (EV). This is to support overnight charging, when electricity rates are low and vehicles are ordinarily not in operation; overnight charging typically lends itself to less costly EVSE due to the lower power usage required to charge a vehicle over a long dwell time. For use cases with higher energy needs and/or less available dwell time for charging, higher-power chargers may be required to meet the energy needs of EVs.

Regardless of the quantity or power of charging equipment, it is important to keep in mind the additional space necessary for charging dispensers, transformers, and other considerations which may change a site's traffic pattern or "flow."

It is recommended that any chargers installed are networked, which means they include the capability to communicate over cellular networks. Most businesses choose to install networked chargers, due to access control, ensuring that only the fleet's service vehicles can charge at these chargers. Alternatively, fleets can install "behind the fence" non-networked charging in a secure location only accessible to fleet vehicles, assuring the same charging restrictions and availability. However, networked chargers can provide a bevy of technical information, including duration of charge and charge rate, useful for operational planning and decision- making.

Inductive (wireless) charging equipment, which uses an electromagnetic field to transfer electricity to an EV without a cord, is now commercially available as an aftermarket add-on, and has the potential to support rapid medium- and heavy-duty vehicle (MHDV) charging at depots and in warehouse environments where trucks park for extended periods of time, such as loading bays. Spreading a charging schedule across as many hours as possible will often lead to the lowest capital and operational cost; thus, it is important to weigh various charging solutions against business needs. The next section describes in greater detail some solutions for how this can be addressed.

Charging Equipment

EV charging equipment is classified by battery charging rates. Time to charge will vary depending on battery state of charge, total energy storage, the type of battery, and the type of charging equipment. Charging time can range from less than 20 minutes to 20 hours or more, depending on these factors.

There are three types of charging: Level 1, Level 2, and Level 3 (direct current or DC fast). Level 1 charging is the slowest method and uses a standard alternating current (AC) wall outlet. It adds 2 to 5 miles of range per hour of charging. Because of its slow rate, Level 1 charging is typically only used at home for personal vehicles or workplaces. Level 2 is another AC method that is significantly faster than Level 1. Level 2 is the most common method of charging as it allows most light- and medium-duty vehicles to charge overnight while also being significantly cheaper and easier to install than Level 3 chargers. Level 2 chargers are most commonly found serving commercial vehicles and in public places like parking garages, shopping centers, and tourist attractions. Level 3 DC fast charging is the fastest method of charging, but also the most expensive for both the charger and infrastructure required. These chargers are typically only recommended for heavy-duty trucks and vehicles that dwell for a few hours or less.

Across the United States, there are four major plug types: J1772 ("J-plug"), Tesla (also known as North American Charging Standard or NACS, or SAE J3400), CHAdeMO, and CCS.

- » The J1772 standard is used for Level 1 and 2 AC charging.
- » Tesla is used for Level 2 and 3.
- » CHAdeMO and CCS are used primarily for Level 3 DC fast charging.

While other proprietary plugs exist for MHDVs, these four represent the majority of those in use. The U.S. Department of Transportation National Electric Vehicle Infrastructure (NEVI) Program has standardized federally funded plugs across Level 2 and Level 3 charging, helping build out a national network of publicly-available charging equipment with predictable plug configurations.

In 2022, Tesla opened its previously proprietary charging standard to other EV manufacturers. In the coming years, its NACS will become the most prevalent charger connection. This connector is also referenced as SAE J3400. All connector types are shown below in Figure 1, but fleets should anticipate a growing share of vehicle options to utilize the NACS standard.

Industry leaders have introduced the concept of the Megawatt Charging Solution, designed to provide higher levels of power needed by MHDVs over a shorter period of charging time. Megawatt chargers require significant infrastructure investment (1–3 million volt-amperes or MVA) and may allow for faster adoption of EVs for long-haul trucking. However, most local and regional delivery businesses can be supported by Level 2 or DC fast chargers.

Туре	Level 1 Charging	Level 2 Charging	Level 3 DC Fast Charging	Megawatt
Connector	J1772	J1772 Tesla/ NACS/ SAE J3400	CHAdeMo CCS Tesla/ NACS/ SAE J3400	MCS
Voltage	120 V AC	208–240 V AC	400 V-1000 V DC	1–3 kV A
Power Output	1 kW	7 kW–19 kW	50–350 kW	900 kW+

FIGURE 1 TYPES OF CHARGERS

Managed Charging

Energy management can greatly decrease operational costs associated with fleet electrification. Managed charging, sometimes called "smart charging," entails the purchase and use of EVSE that can actively track and modulate charging, and a subscription for energy management software provided by the EVSE manufacturer or network provider to keep consumption levels within a predetermined range. While there are additional up-front and monthly costs associated with these technologies, their long-term benefits should also be considered from a total cost of ownership perspective. Depending on the design of local electricity rates, electricity pricing can be based upon the time of day during which electricity is used, where marginal pricing is greater during times of high demand and lower when strain to the grid is at its lowest. Fleets may also be exposed to demand charges, which are increased electricity chargers incurred from large, simultaneous power draws—such as when multiple heavy-duty trucks plug into fast charging at the same location at the same time. However, charging when electricity costs are lowest is not always feasible or operationally convenient for fleets. Managed charging software automates charging to coincide with dwell times while enabling fleets to benefit from lower electric rates and/or mitigating demand charges.

Fleet 4 could utilize managed charging when their vehicles have extended downtime. This could allow them to charge the vehicles using less equipment rather than procuring one charging port per vehicle.

On-Route versus Depot Charging

Most commercial EV deployments currently in operation rely solely on depot charging, or a "return-to-base" schedule where a fleet keeps vehicles parked at one location owned/ leased by the organization operating those vehicles. While policy efforts and Federal funding are advancing the development of strategically sited on-route fast charging and public charging hubs, it is recommended that current EV deployments plan for on-site depot charging, where feasible.

The Alternative Fuels Database, provided by the U.S. DOE, includes a <u>tool</u> to find publicly available charging stations, as does the similar <u>PlugShare</u> tool. Users can also map a route, similar to Google Maps, and see all charging stations along the route. These tools compile data from many networks of charging stations, such as <u>ChargePoint</u>, <u>Electrify America</u>, <u>EVgo</u>, and <u>Tesla</u>. By clicking on a charging station, one can view the number of available charging ports, as well as the type of charging connector.

It is important to note that not all charging stations listed on these sites will be appropriate for charging MHDVs. Most Class 2b and Class 3 vehicles will be able to use charging stations designed for light-duty vehicles, but Class 4–8 vehicles are often too large for typical light-duty vehicle parking spaces, and may require higher power levels to recharge quickly. It is anticipated that most public charging stations for medium- and heavy-duty trucks will require power levels of 150–350kW or more per port, paired with pull-through charging stalls and

ample clearance. These may not be available at stations that appear in the DOE or PlugShare tools.

Few DC fast chargers are currently available on-route, and those that do exist may not be able to accommodate a Class 8 truck. The network of available chargers will continue to grow, however; active chargers and hours of operation are updated in these tools on a monthly basis. An example charger that would be convenient for Fleet 4 is shown in Figure 2.

Public chargers such as ChargePoint or EVgo typically require that drivers use a mobile application to interact with the charger and pay for their charge, either through the app itself, or with a credit card at the charger. In 2023, the NEVI program introduced standards for future EVSE installation including provisions that stations must implement non-proprietary charging ports, accept open-access payments such as pay by phone or contactless credit/ debit card, be located along designated FHWA <u>Alternative Fuel Corridors</u>, and be publicly available.

Fueling/Charging Cost Analysis

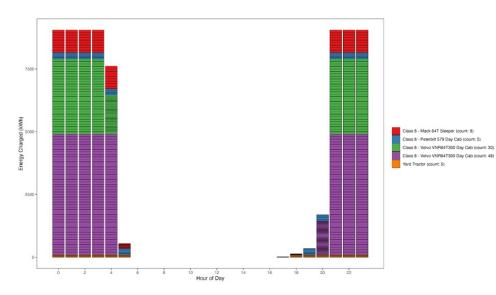

A charging analysis was performed for electrification scenarios for Fleet 4 using CALSTART's Charging Infrastructure Optimization (CHARIOT) Tool. The CHARIOT tool aims to optimize Fleet 4's charging schedule, to find a schedule that works well with fleet operations while achieving lowest possible energy cost. It also provides a projected energy flow of a fleet's energy consumption and, when applicable, potential for on-site energy generation (e.g., solar power with battery storage) to get a sense of a site's energy independence and grid reliance. Fleet 4's electricity is provided by Central Maine Power (CMP).

The CHARIOT tool was used twice for each warehouse: once using Versant's high peak timeof-use (TOU) rate (\$3.55/kWh) and once using a flat TOU rate (\$0.12/kWh).

Daily Charging Load Profiles

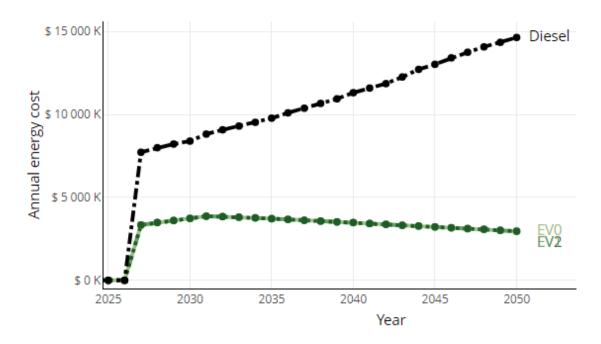

Figure 3 shows what daily charging profiles (energy demand by hour) might look like for this fleet. Total annual energy cost and cost per mile for diesel versus electric vehicles are shown in Figure 4 and Figure 5, respectively for a flat time-of-use rate scenario. Based on the anticipated energy needs of 93 electric trucks at the warehouse compared to 93 diesel trucks, Fleet 4 would be estimated to achieve significant reductions to their annual energy costs. Because of the reduced cost of charging compared to diesel fuel, Fleet 4 could expect a significantly decreased cost per mile of operation.

FIGURE 3 DAILY CHARGING LOAD PROFILES—ALL VEHICLES

EVSE FINANCING

Federal Incentives

Commercial Clean Vehicle Tax Credit

The Federal Government's adoption of the Infrastructure Reduction Act (IRA) enacted new Federal tax credits (IRC Section 45W) for commercial clean (electric or hydrogen fuel cell) vehicles in 2022. Eligible entities include businesses and tax-exempt organizations that purchase commercial clean vehicles between January 1, 2023, and before January 1, 2033. Heavy-duty vehicles with a gross vehicle weight rating (GVWR) of 14,000 lbs. or greater are eligible for a tax credit up to \$40,000, or 30 percent of the incremental cost of the vehicle as compared to a gasoline or diesel vehicle, whichever is lower. Applicable electric vehicles must have a battery with at least 15 kWh of capacity and be made by a qualified manufacturer (see the IRS's list for examples). For tax exempt entities, such as schools, governments, or non-profit organizations, the tax credit is available through a mechanism commonly known as direct, or elective, pay.

Alternative Fuel Infrastructure Tax Credit

Beginning on January 1, 2023, installation of EV charging equipment is eligible for a tax credit of 30 percent of the installation costs (or 6 percent in the case of property subject to depreciation), not to exceed \$100,000. Permitting and inspection fees are not included in covered expenses. As above, tax-exempt entities are eligible to claim these credits through direct or elective pay.

These tax credits are only available to business locations and tax-exempt entities with the following census tract requirements:

- » A population census tract where the poverty rate is at least 20 percent.
- » Metropolitan and non-metropolitan area census tract where the median family income is less than 80 percent of the State median family income level.

Fleets should work with their charging infrastructure installers to determine eligibility by identifying their census tract using <u>this tool</u> and determining if it is included in the <u>IRS's list</u>. If eligible, <u>tax form 8911</u> should be completed.

State Incentives

Efficiency Maine Medium- and Heavy-Duty Vehicle Incentive Pilot

In October 2024, the quasi-state agency Efficiency Maine Trust launched a pilot program to demonstrate potential use cases and performance of zero-emission MHDVs in Maine. Awards will be issued in three rounds, with applications open through the end of February 2025, with the possibility of further rounds of funding in the future. In order to be eligible, applicants must be based in Maine and already own a Class 3 to 7 vehicle in their fleet. The maximum award for different vehicle classes is shown in Table 3.

TABLE 3 EFFICIENCY MAINE INCENTIVE LEVELS

Vehicle Class	Maximum Award
Class 3	40% of purchase price up to \$40,000
Class 4	40% of purchase price up to \$60,000
Class 5	50% of purchase price up to \$80,000
Class 6	50% of purchase price up to \$100,000
Class 7	50% of purchase price up to \$120,000

Along with awards for vehicle purchases, the program also offers incentives for Level 2 charging and professional services such as consulting. For further information, and to apply, fleets should visit <u>the program website</u>.

RESULTS

Total Cost of Ownership

Calculating the total cost of ownership (TCO) for a vehicle offers fleet owners information to evaluate direct and indirect costs of EV purchases, as well as potential savings over the life cycle of purchased vehicles. The transition to EVs involves a shift in perspective regarding TCO components. Traditional internal combustion engine (ICE) vehicle costs are usually presented as capital cost for vehicles and dollar per gallon (\$/gal) costs for fuel, as well as lifetime maintenance expenses. An analysis of TCO for EVs must consider power output, \$ per kilowatt, grants and incentive programs, and planning and installing EVSE. While EVs are typically more expensive upfront, they are often less expensive to operate and maintain than

comparable ICE vehicles; in many cases, these operational savings can offset higher upfront costs across the lifespan of the vehicle, resulting in a positive TCO.

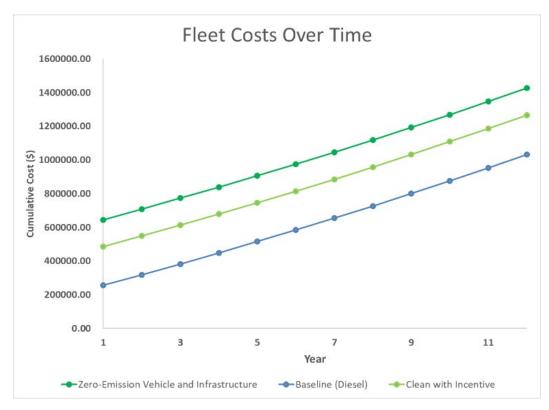

TCO is calculated by combining the vehicle capital and operating costs over a set period of operations. For this analysis, the vehicle price points came from industry averages. Calculations assume a purchase in 2025 and a 12-year vehicle life, which is average across Maine trucks in this class. The results represent one vehicle in each duty cycle. Calculations accounted for the Efficiency Maine Trust vehicle incentives and the Federal Commercial Clean Vehicle tax credit. The results are estimates and actual cost differences may vary.

Each TCO scenario is modeled with a capital procurement cost for the diesel versus electric model and does not include any vehicle resale or residual values. The Federal tax credit is detailed in the <u>Federal Incentives</u> section and, along with Maine State incentives, is taken into consideration when modeling cumulative costs over time. For simplicity, the TCO calculation includes procurement of EVSE and infrastructure upgrades based on the cost of a single port. Infrastructure upgrade costs are calculated per location, not per vehicle. Those costs are modeled in the <u>Fueling/Charging Cost Analysis</u> section. The included costs are vehicle procurement, sales tax, Federal excise tax, maintenance, fuel, and insurance costs.

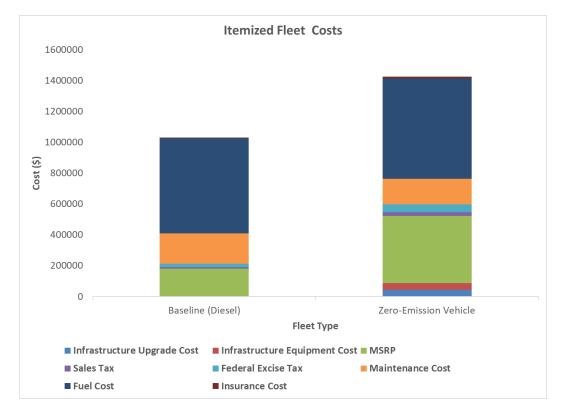

Volvo Day Cab

The Volvo day cabs at Fleet 4's warehouse have an average annual mileage of 96,000 miles and operate 365 days per year, meaning their daily driving distance is about 263 miles. Figure 6 shows cumulative costs over time and Figure 7 shows itemized total costs.

This TCO analysis compares a Class 8 diesel-powered tractor trailer priced at \$170,300 with an electric tractor trailer priced at \$435,000. It assumes a \$4.00/gallon price of diesel and an \$0.18/kWh price of charging. The infrastructure cost is priced at \$87,050 for the costs of one Level 3 DC fast charging port hardware, installation and local infrastructure, and utility side make-ready costs. This cost is included in the upfront capital costs of the vehicle purchase.

The modeled incentive is \$120,000 off the vehicle purchase price, reducing the capital procurement cost to \$315,000. The Commercial Clean Vehicle Tax Credit removes \$40,000 more (30 percent of the MSRP, capped at \$40,000), reducing the procurement cost further to \$275,000.

The results indicate that the electric trailer's payback period exceeds its expected life due to significantly higher upfront capital costs. The electric trailer still produces an estimated 18 percent reduction in annual maintenance costs (\$2,984) due to savings on items like oil and filter changes, and reduction in parts failure (fewer moving parts). Itemized costs are shown in Table 4.

Cost Components	Baseline	ZEV
Manufacturer's Suggested Retail Price	\$180,000	\$435,000
Sales Tax	\$9,900	\$23,925
Federal Excise Tax	\$21,600	\$52,200
Maintenance Cost	\$196,948	\$164,124
Fuel Cost	\$618,177	\$652,019
Insurance Cost	\$4,698	\$11,353

Fleet Emissions

Maine's transportation sector is the largest source of greenhouse emissions in the State, and medium- and heavy-duty trucks account for 27 percent of these emissions.¹ Providing power to vehicles via electricity is significantly less polluting than diesel fuel, especially in areas served by low-carbon sources of electricity generation. Renewable resources powered

¹ Rocky Mountain Institute. "<u>RMI Analysis: With Smart Policy, Truck Electrification Is Within Reach</u>." Accessed October 2024.

64 percent of Maine's total electricity net generation, and wind provided the largest share at 23 percent of the State's total net generation, in 2022.²

An analysis of Fleet 4's direct exhaust emissions was performed using the U.S. Environmental Protection Agency's Diesel Emission Quantifier tool. The analysis combines the average annual mileage traveled by all 97 vehicles in the fleet. Converting Fleet 4's vehicles to ZEVs would eliminate all of these direct emissions.

TABLE 8 INTERNAL COMBUSTION ENGINE FLEET EMISSIONS

Pollutant	Annual Emissions (Short Tons/Year)
Carbon Monoxide (CO)	13.06
Nitrogen Oxides (NO _x)	19.285
Particulate Matter (PM)	0.034
Carbon Dioxide (CO ₂)	5,909

IMPLEMENTATION CONSIDERATIONS

Energy Storage and Resiliency

Power outages are always a possibility at fleet depots, regardless of grid advancements and fidelity. Fleets should consider contingencies for maintaining operations of electric trucks in the event of a long-term power outage. Today's electric vehicles do not necessarily require electricity from the grid to be available to properly fuel. There are means of fueling battery-electric vehicles using energy storage solutions, most commonly batteries, which are safer than storing flammable fossil fuels on site. Critical vehicle operations may consider other forms of backup power to ensure charging access, including generators.

Many consumers have asked whether EVs can be used in an emergency to provide backup power to homes, offices, and other facilities. For a vehicle to provide backup power, there are several additional considerations: whether the vehicle is designed for 'bidirectional charging', meaning that the vehicle can output power, and whether the facility has appropriate two-way charging equipment. The Ford F-150 Lightning is equipped to support

² U.S. Energy Information Administration. <u>State Profile and Energy Estimates</u>. Accessed October 2024.

bidirectional charging, and Ford supports claims that the truck can provide up to 100 kWh of power on a single charge, which is enough to power an average house for three days (30 kWh per day).

Preheat/Precool

One consideration often overlooked in commercial EV operation is the energy use associated with climate control, either for the operator or for the goods themselves. Idle time spent bringing a cab to a comfortable riding temperature uses energy otherwise intended for moving the vehicle along its intended route. The energy used to heat or cool the vehicle cabin may consume a significant amount of the vehicle's battery capacity. Preconditioning while vehicles are connected to chargers at the depot is a simple approach to providing comfortable conditions and extending driving range during winter and summer. These types of considerations are important to factor in, and experiment with, during a fleet's initial deployment.

"Vampire" Energy

Vehicles of all kinds are meant to be driven; they benefit from regular usage by foregoing the potential negative impacts of remaining idle for extended periods. One such impact to commercial EVs is what is known as "vampire" energy, where a vehicle's battery will slowly deplete while it remains unplugged and idle. This is normal behavior and not an indication that anything is malfunctioning. Rather, this is an expected effect resulting from a combination of onboard electronics that remain on or in stand-by, as well as the natural chemical reactions occurring in a vehicle's battery.

Best practices for long-term battery health include keeping a vehicle's battery charged to 80 percent when possible and taking measures to ensure its state of charge does not regularly fall below 20 percent while idle. Managed and networked charging infrastructure can help fleets keep battery state of charge within this optimal range. For smaller EV deployments and fleets involving just a few vehicles, this also may be achievable through effective training and communication with staff on-site.

REFERENCES

CALSTART's Zero-Emission Technology Inventory (ZETI) is a public online interactive dashboard containing the status and anticipated timing of commercial availability for zero-emission MHDVs across a range of vehicle platforms and key global regions. ZETI was the primary tool used to find equivalent medium and heavy-duty electric vehicle models that could replace the current fleet inventory.
