Safety Performance on Maine's Rumble Strip Corridors

Background:

On Maine's rural roads, many crashes and MOST fatalities (70% of the total) result when a vehicle leaves its designated travel lane (going either left or right) and is involved in a *Lane Departure* crash. That crash may be further described either as a Went Off Road or a Head On type crash. Although far fewer Head On crashes occur compared to the number of Went Off Road crashes, the likelihood of a serious injury or a fatality in a Head On crash are very high. In Maine, during the past 10 years, there have been over 8,000 Head On crashes and those resulted in 355 fatalities and more than 1,100 serious injuries. In recent years, there has been an average of 33 Head On fatalities occurring annually. That number spiked up in 2014 to 46, but was back down to 30 in 2015.

Vehicles leave their proper lane due to a variety of driver contributing factors: speed, alcohol/drugs, distracted driving, fatigue/falling asleep, medical episodes... also wintry or wet roads contribute to some incidents.

Preventing deadly Head On crashes has been a continuing focus for MaineDOT. Center line rumble strips have been found to be the best mitigation to prevent these crashes. Rumble strips provide immediate feedback to the driver at that point of lane deviation and are intended to alert that driver to correct course. While smart cars are coming onto the market, and some new cars feature lane departure alert systems, it will still be a long time before all vehicles become interactive with the driver or self-correcting when things go wrong. Rumble Strips have been a proven way to alert erring drivers that they are leaving their lane – regardless of any available on-board vehicle technology.

Initially, Maine was taking a reactive approach to installing centerline rumble strips. If there was a history of high frequency Head On crashes on a section of road, then rumble strips were considered. MaineDOT first installed center line rumble strips on two non-interstate corridors in 2006 – Route 1, Woolwich and Route 4, Turner.

Predicting where Head On crashes are going to occur is difficult since locations will vary based on wherever that problem driver behavior is exhibited (e.g. a driver could decide to text anywhere). Due to that random crash occurrence aspect, MaineDOT evaluated Head On crash activity based on overall road characteristics/risk factors rather than the changing perspective of where crash clusters happened to be occurring in a given review period.

One way to classify roads for performance evaluation is by road ownership – there are four categories: Toll Roads; State Highway; State Aid (shared State/Town responsibility); and Townway (local). State Highway roads represent about 17% of the state's non-Toll roadway mileage, but experience 55% of the non-interstate fatalities, and 80% of the Head On fatalities. On a fatalities/mile basis, State Highways have double the rate than that for State Aid Roads, and nearly 10 times that of the Townway rate. These higher State Highway fatality rates are a product of far higher traffic volumes and generally higher travel speeds. When analyzing State Highway fatality trends, Head On collisions from 2011 through 2015 accounted for a higher percent of fatalities than did Went Off Road crashes (35.0% of total fatalities vs. 33.2% respectively).

MaineDOT further conducted system-wide crash reviews to identify road qualities where Head On crashes are most concentrated – a systemic approach. MaineDOT also classifies roads is into six levels of Highway Corridor Priority (HCP). HCP 1 for example would be a road of top importance including economic significance, such as interstate highways. HCP 6 are local roads. Crash data was screened to determine if Head On crashes were concentrated on certain Highway Corridor Priorities (HCP), speed limits, and/or AADT levels. See Table 6. for data comparisons.

Head On crashes are the most deadly crash type on non-interstate HCP 1 and 2 roads. Drilling further down, a significant portion of the HCP 1 and 2 Head On fatalities (46 of the 104 or 44.2%) were occurring on roads having traffic volumes of 6,000 AADT or more, and posted speed limits above 45 mph. These defined road sections represented about 2% of the roadway network but had 28% of the Head On Fatalities. Mitigating 2% of the road system to address 28% of the highest risk Head On corridors provided focused direction on how to prioritize and get the most benefit out of limited resources. This systemic approach to invest in rumble strips at the most crash-likely priority roads was adopted. This narrow selection of roads had the highest percentage of Head On crash type fatalities (49%) and the highest density of fatal crashes over a five year period (9.5 fatalities over a 5 year period/100 miles of roadway).

From 2006 through 2014, Maine had installed a total of about 55 miles of centerline rumble strips. In 2015 alone, MaineDOT added another 90 miles of centerline rumble strips (bringing the state-wide total to 145 miles) and plans to systemically add about another 175 miles in 2016. The systemic corridor selection process is described further below.

MaineDOT's policy on installing centerline rumble strips includes installing them in passing zones. These sections obviously are where drivers intentionally/legally need to cross the center line. However, rumble strips are still needed on these straight portions of roadway since those driver errors noted above do occur on every type of road. Straight roadways with wide shoulders are locations where a driver may get a false sense of comfort and loosen up their attention to the driving task. MaineDOT does provide gaps in the rumble in passing zones to smooth the way for motorcycles to safely pass.

Noise concerns are considered when selecting rumble strip locations, and based on MaineDOT rumble strip guidelines noted above, most densely developed corridors would not be eligible since they are usually in lower posted speed areas. Hotels, motels and campgrounds normally should be gapped unless otherwise agreed to with the owner/operator. Rumble strip noise complaints up to this time have been very minimal. No other maintenance, plowing, or pavement condition problems have been identified related to installing centerline rumble strips. Sealer is applied immediately after rumbles are cut into the pavement. At this time, there is no programmatic plan to install edge line rumble strips installations of these will be on a select basis.

Safety Performance:

Comparing before and after safety performance has shown clear safety improvements, not only for Head On collisions, but even Went Off Road crashes experienced a noticeable decrease. National performance analysis indicates a long term 40-60% expected head on fatality reduction. Tables 2 through 4 show Crash, Fatality and Incapacitating Injury activity *Before* and *After* rumble strip installation work.

This study looked at as many as 10 corridors (Listed in Table 1) that were rumble stripped between 2006 and 2014. These corridors total about 55 miles. Since the installation years vary and the rumble strip location selection process is based on most efficient benefit per mile of roadway, the *Before* and *After* safety performance was also based on crashes/mile performance comparisons. This report reviewed *Before* and *After* results from the following perspectives:

- 1. ALL Corridors having Rumble Strips installed in 2014 and earlier: comparisons are pro-rated on Miles and *Before/After* Years of Miles Exposure (10 Corridors, 55.56 miles) Corridor miles were annualized based on the number of years of crash history was available, and no more than 10 years of *Before* history was used, and so far, the max of 9 years *After*.
- 2. Corridors evaluated on 5 Years *Before/After* Crash Experience (Only 2 Corridors had enough *Before* and *After* history for this evaluation, 8.05 miles)

- 3. Corridors evaluated on 3 Years Immediately *Before/After* Crash Experience (5 Corridors had adequate length of *Before/After* history 16.54 miles)
- 4. **Corridors evaluated on 3 Years Immediately** *Before* and the most recent **3 Years** *After* (2013 through 2015) Crash Experience (5 Corridors - 16.54 miles)

Findings (See table 5):

- The most significant improvement was seen in the reduction of **fatalities**, where even in the worst performing data comparison set described above, fatality rates were reduced by 90%. This is far above what national studies have shown, so Maine's results will likely moderate somewhat with time and more data development.
- Head On Crash rates reduced between 37.5% to 78.9%, depending on the study time frame, and Incapacitating injury results ranged from an increase of 100% to a reduction of 50%. These latter results obviously show a lot of variability and will need to be watched as we have more data to work with.
- Went off Road safety performance improved in all measured safety categories, so although Centerline Rumble Strips are largely thought of as a Head On crash mitigation, they provide additional safety benefits for other crash types as well. Crash rates were down between 18.8 and 36.5%; Fatalities rates down, but there was little data available, so that aspect will need future monitoring; and incapacitating injury rates were down between 50 and 75%.

Next Steps – what's underway for 2016 and beyond:

Maine's systemic approach described above identified roads that were at the highest serious risk for Head On crash risk – these roads met the following criteria: Highway Corridor Priority 1 & 2; Posted speed 45 mph or greater; and ≥ 6,000 AADT.

Once that criterion was defined, MaineDOT's road system inventory was queried and all roads that met those qualifications were identified. That select inventory was paired with a review of past and near future paving work – both identifying dates of upcoming paving work and the type of pavement treatment. That combined inventory was then toured. The review team included pavement specialists, Regional staff, Highway Design and Safety. A resulting Rumble Strip work plan was established that charts out Rumble Strip needs through 2019, with 2016 being the most aggressive year in terms of planned miles of installation.

Improving Safety on Maine's Roads

MaineDOT developed a Rumble Strip brochure (left) to inform the public about the benefits of Rumble Strips. (Below) Center line rumble strip installation on Route 1A, Dedham.

MaineDOT

To learn more about rumble strips, a brochure is available at <u>http://www.maine.gov/mdot/safety/docs/rumblestrip-brochure-general.pdf</u>
