Use of Warm Mix Asphalt Pavement on Interstate 95, Carmel to Hampden, Northbound

Introduction

A number of new technologies have been developed to lower the production and placement temperatures of hot-mix asphalt (HMA). Generically, these technologies are referred to as warm-mix asphalt (WMA). In Europe and to a lesser extent in North America, WMA has been used in all types of asphalt concrete, including dense-graded, stone matrix, porous, and mastic asphalt. It has also been used in a range of layer thicknesses, and sections have been constructed on roadways with a wide variety of traffic levels. WMA is rapidly being adopted by many states in the country.

WMA Technology

There are currently over twenty different commercial technologies used to produce WMA. Several methods are used to classify the different technological approaches to WMA. One method of classification is by the degree of temperature reduction. (See Appendix II for a list of commercial technologies and classifications.) Warm asphalt mixes are separated from half-warm asphalt mixtures by the resulting mix temperature. There is a wide range of production temperatures within warm mix asphalt, from mixes that are 30 to 50 °C (55 to 85 °F) below HMA to temperatures slightly above 100 °C (212 °F).

Another way to classify the technologies is by how they reduce viscosity. Those that use water and then others that use some form of organic additive or wax to affect the temperature reduction. Processes that introduce small amounts of water to hot asphalt, either via a foaming nozzle (Double Barrel Green) or a hydrophilic material (Zeolite), or damp aggregate (Low Energy Asphalt), rely on the fact that the steam expands the asphalt binder providing improved mix characteristics. Chemical (Evotherm, Rediset WMX) and organic (Sasobit) additives use different mechanisms to provide improved mix characteristics such as enhanced viscosity, coating, adhesion and workability.

Benefits of Warm Mix Asphalt

Reduced emissions. Data indicate that plant emissions are significantly reduced in producing WMA. Typical expected reductions are 30 to 40 percent for CO2 and sulfur dioxide (SO2), 50 percent for volatile organic compounds (VO C), 10 to 30 percent for carbon monoxide (CO), 60 to 70 percent for nitrous oxides (NOx), and 20 to 25 percent for dust. Actual reductions vary based on a number of factors. Technologies that result in greater temperature reductions are expected to have greater emission reductions.

In addition to lowered plant emissions, the jobsite release of aromatic hydrocarbons is reduced for WMA. Industry tests show that releases of asphalt aerosols/fumes and polycyclic aromatic hydrocarbons (PAHs) is lower for WMA as compared to HMA. Potentially a 30 to 50 percent reduction. It should be noted, however that the worker exposure data for these compounds from conventional HMA are below the current acceptable exposure limits.
**Reduced fuel usage.** Burner fuel savings with WMA typically range from 11 to 35 percent. Fuel savings could be higher (possibly 50 percent or more) with processes such as low-energy asphalt concrete (LEAC) and low energy asphalt (LEA) in which the aggregates (or a portion of the aggregates) are not heated above the boiling point of water.

**Paving benefits.** Paving-related benefits discussed included the ability to pave in cooler temperatures and still obtain density, the ability to haul the mix longer distances and still have workability to place and compact, the ability to compact mixture with less effort, and the ability to incorporate higher percentages of recycled asphalt paving (RAP) at reduced temperatures. In addition since the mix is produced at lower temperatures there is less aging to the asphalt binder which could result in improved long term durability. It has also been documented on some WMA projects that there was less mat segregation.

**Cost Considerations**

WMA technologies may increase cost, through plant modifications or additive costs. Although there is potential to reduce plant operational costs in fuel reduction, these savings may not offset the increased material costs. The potential to increase RAP usage without sacrificing performance could reduce the cost per ton of WMA.

---

**Project Location**

In 2010 a highway preservation project along Interstate 95 utilized warm mix asphalt (WMA) pavement. The project, from Carmel to Hampden (PIN 16821.00), begins 2.7 miles northerly of the Carmel town line at station 00+00 and extends northerly 5.91 miles to station 312+25. The project location is shown on the map.
**Project Scope**

The project involved milling 1 ¾ inch of existing pavement and replacing with 1 ¾ inch of warm mix asphalt. The scope of the paving consisted of a ½” minimum shim with 1 ¼ “overlay. The WMA was placed using conventional paving equipment: Blaw-Knox 3200 paver, 2 DD 90 vibratory rollers, Dynapac pneumatic roller, Hamm HD 90 roller, and Weiler Material Transfer Vehicle. Roadway millings were stockpiled to be used as Classified RAP; up to 20% RAP was added to the mix.

Approximately 1 mile at the beginning of the section was paved with HMA as a control section, thereafter WMA was placed. The WMA section was started with the asphalt at higher temperatures, then asphalt temperatures were reduced to WMA temperatures. Target temperature range was 250° – 325° F. The typical section is below.

The control section begins at approximately Route-Log-Mile (RLM) 168.86 and ends at RLM 169.86. Correspondingly the WMA would begin at RLM 169.86 and end at approximately 174.77. The table below shows the ride, rut and pavement condition measurements based on Automatic Road Analyzer (ARAN) network collection data from 2009, 2010, and 2011.

Materials

The asphalt binder used was PG 64-28 with SonneWARMix™ additive used at the paving plant to create the warm mix properties. SonneWARMix™ is a paraffinic hydrocarbon compound, according to its MSDS data sheet.

Material Costs

The total project cost was approximately $2.23 million for the resurfacing of the 5.91 mile long section of Interstate 95. Asphalt bid quantities and estimated costs are shown in the following table. The following selected pay items are included here for relative comparison only and do not reflect any asphalt price escalators.

Conclusions

The project is a field demonstration for Warm Mix Asphalt. It is noteworthy that this project utilized an asphalt additive to give the asphalt its WMA properties. Future evaluations could compare this section with other pavements that utilized other WMA technologies. The rapid adoption of WMA by many states across the country has been accompanied by some concerns on durability. One concern is that WMA may be more susceptible to moisture damage (stripping). The evaluation of this project should include observations to determine if moisture deterioration is a problem or not. This project, along with other MaineDOT WMA projects will be monitored over a five year period for pavement performance. Work shall include field visits and observations of distresses, analysis of rut and ride data from the ARAN and if needed subsurface investigations (coring, FWD, etc.) should the pavements have premature failure. Some wheel path scour is visible on this test project, nevertheless, the performance of this WMA pavement is comparable with conventional HMA pavement.

The Special Provision 401 – Hot Mix Asphalt Pavement, has been modified with the following revisions. All sections not revised by this Special Provision shall be as outlined in the Special Provision 400 Pavements, section 401 – Hot Mix Asphalt Pavement. References to Standard Specifications, Special Provisions, or other documents, shall be determined as the most current version available at the time of bid. All references or conditions applied to Hot Mix Asphalt (HMA) pavements shall be replaced with Warm Mix Asphalt (WMA) unless otherwise amended or revised within this specification.

401.01 Description The Contractor shall furnish and place one or more courses of Warm Mix Asphalt Pavement (WMA) on an approved base in accordance with the contract documents and in reasonably close conformity with the lines, grades, thickness, and typical cross sections shown on the plans or established by the Resident. The Department will accept this work under Quality Assurance provisions, in accordance with these specifications and the requirements of Section 106 – Quality, the provisions of AASHTO M 323 except where otherwise noted in sections 401 and 703 of these specifications, and the Maine DOT Policies and Procedures for HMA Sampling and Testing.

MATERIALS

401.03 Composition of Mixtures This section has been amended as follows:

For the purposes of comparative testing, a HMA JMF shall be submitted for the establishment of a Control strip. The control strip section shall be constructed with an approved JMF, submitted without WMA technology or additives. The HMA design shall be submitted with the same aggregate, aggregate percentages, asphalt supply, and asphalt target percentages as the WMA JMF.

401.031 Warm Mix Technology
The Contractor shall specify the method or type of WMA technology to be utilized to produce mixtures for use on Department projects. Methods or technologies shall generally be at the Contractors option, but will be limited to proven, Agency and Industry accepted practice. Examples of acceptable methods are listed:

Option A - The use of organic additives such as a paraffin wax and or a low molecular weight esterified wax. Wax derived additives shall be introduced at the rate recommended by the manufacture. Percentages shall be limited at a rate as to not impact on the binder’s low temperature properties. Wax derived additives shall be introduced into the hot asphalt binder at the asphalt suppliers facility, or asphalt mixture plant and fully blended using a tank agitator / stirrer. Minimum placement temperatures shall be as per manufactures recommendations. A Quality Control Plan shall be submitted for approval by the Department.
February 3, 2010

**Option B** – The use of a manufactured synthetic zeolite (Sodium Aluminum Silicate). Sodium aluminum silicate additives shall be introduced at a rate recommended by the manufacturer. Sodium aluminum silicate additives shall be introduced into the hot mix plant mixing chamber by mechanical means that can be controlled and tied directly to the hot mix asphalt plants rate of production. Minimum placement temperatures shall be as per manufacturers recommendations. A Quality Control Plan shall be submitted for approval by the Department.

**Option C** – The use of a chemical additive technology and a "Dispersed Asphalt Technology" delivery system. This process utilizes a dispersed asphalt phase (emulsion) in asphalt mixture plant at a rate recommended by the manufacturer. This additive shall be introduced into the hot mix plant mixing chamber by mechanical means that can be controlled and tied directly to the hot mix asphalt plants rate of production. Minimum placement temperatures shall be as per manufacturers recommendations. A Quality Control Plan shall be submitted for approval by the Department.

**Option D** – The use of a controlled asphalt foaming system. This process utilizes an injection system to introduce water to the asphalt stream and “expand” the asphalt prior to mixing with the aggregate in asphalt mixture plant at a rate recommended by the manufacturer. This shall be introduced into the plant mixing chamber by mechanical means that can be controlled and tied directly to the asphalt plants rate of production. Minimum placement temperatures shall be as per manufactures recommendations. A Quality Control Plan shall be submitted for approval by the Department.

**401.04 Temperature Requirements** After the JMF is established, the temperatures of the WMA mixture shall conform to the following tolerances:

- In the truck at the mixing plant – allowable range determined by manufacturer
- At the Paver – allowable range determined by manufacturer

Mixture, placement and volumetric testing details, including temperatures, shall be included in the project specific QCP, and submitted to the Department prior to any work.

**401.18 Quality Control Method A, B & C** – This section has been amended as follows:

**Establishment of Control Strip** - The Contractor shall place a control strip for each mixture type consisting of Hot Mix Asphalt Pavement produced without warm mix technology. Prior to the placement of the control strip a passing verification test is required. The control test strip shall be placed over the full width of the travel way section, not to exceed 1000 ton production per lane. The control strip will not be excluded from QA analysis, but will be evaluated in accordance with Section 401.03. The Contractor shall notify the Department at least 48 hours in advance of placing the control strip.
Control strips shall be required for all mixtures to be utilized in the contract. Wearing, shim, or lower lift base mixtures shall be placed as required within the control strip limits. A minimum of three mixture samples shall be randomly selected from the control strips and evaluated under Method B criteria. A minimum of three core samples shall be randomly selected from wearing or lower lift base course control strips and evaluated under Method B criteria. After completion of the control strip, the Contractor shall make any final adjustments to the job mix formula in accordance to Standard Specifications, Section 401, subsection 401.03 - Composition of Mixtures, or compaction method. Any changes to the HMA JMF shall result in a change in the WMA JMF to identical target values. Paving operations shall not resume until the Contractor and the Department determines that material meeting the Contract requirements can be produced, and any changes to the Job Mix Formula have been approved by the Department. The Department shall pay for an accepted control strip as determined Section 401.222 – Pay Factor A and B, for this item. A new control strip shall be required if a current JMF is terminated, and a new JMF is started.

Once established, all production methods, equipment, and JMF’s will become part of the QCP. The control strip will allow for any necessary adjustments to the mix design and or plant mixing procedures, as well as for the Department to evaluate the quality of the pavement.
